When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

When the SSI is programmed for MICROWIRE frame format, the default size for transmit data is eight bits (the most significant byte is ignored). The receive data size is controlled by the programmer. The transmit FIFO and the receive FIFO are not cleared even when the SSE bit in the **SSICR1** register is cleared, allowing the software to fill the transmit FIFO before enabling the SSI.

**Register 5: SSI Clock Prescale (SSICPSR), offset 0x010**

The **SSICPSR** register specifies the division factor which is used to derive the SSIClk from the system clock. The clock is further divided by a value from 1 to 256, which is  $1 + \text{SCR}$ . SCR is programmed in the **SSICR0** register. The frequency of the SSIClk is defined by:

$$\text{SSIClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

## Register 6: SSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit sets the mask, preventing the interrupt from being signaled to the interrupt controller. Clearing a bit clears the corresponding mask, enabling the interrupt to be sent to the interrupt controller.

### SSI Interrupt Mask (SSIIM)

**Register 7: SSI Raw Interrupt Status (SSIRIS), offset 0x018**

The **SSIRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

**SSI Raw Interrupt Status (SSIRIS)**

Register 11: SSI Clock Configuration (SSICC), offset 0xFC8

The SSICC register controls the baud clock source for the SSI module.

**Note:** If the PIOSC is used for the SSI baud clock, the system clock frequency must be at least 16 MHz in Run mode.

SSI Clock Configuration (SSICC)

SSI0 base: 0x4000.8000  
SSI1 base: 0x4000.9000  
SSI2 base: 0x4000.A000  
SSI3 base: 0x4000.B000  
Offset 0xFC8  
Type R/W, reset 0x0000.0000

## 15 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture. The LM4F231H5QR microcontroller includes providing the ability to interact (both transmit and receive) with other I<sup>2</sup>C devices on the bus.

The Stellaris® LM4F231H5QR controller includes I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Four transmission speeds:
  - Standard (100 Kbps)
  - Fast-mode (400 Kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Clock low timeout interrupt
- Dual slave address capability
- Clock low timeout interrupt
- Dual slave address capability
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

## 15.1 Block Diagram

Figure 15-1. I<sup>2</sup>C Block Diagram

## 15.2 Signal Description

The following table lists the external signals of the I<sup>2</sup>C interface and describes the function of each. The I<sup>2</sup>C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset, with the exception of the I2C0SCL and I2CSDA pins which default to the I<sup>2</sup>C function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I<sup>2</sup>C signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 644) should be set to choose the I<sup>2</sup>C function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPTCL)** register (page 661) to assign the I<sup>2</sup>C signal to the specified GPIO port pin. Note that the I2CSCL pin should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 623.

Table 15-1. I2C Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                      |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 15.3 Functional Description

Each I<sup>2</sup>C module is comprised of both master and slave functions. For proper operation, the SDA pin must be configured as an open-drain signal. Due to the internal circuitry that supports high-speed operation, the SCL pin must not be configured as an open-drain signal, although the internal circuitry causes it to act as if it were an open drain signal. A typical I<sup>2</sup>C bus configuration is shown in Figure 15-2. Refer to the *I2C-bus specification and user manual* to determine the size of the pull-ups needed for proper operation.

See “Inter-Integrated Circuit (I<sup>2</sup>C) Interface” on page 1339 for I<sup>2</sup>C timing diagrams.

**Figure 15-2. I<sup>2</sup>C Bus Configuration**

### 15.3.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on Stellaris microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I<sup>2</sup>C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 964) is unrestricted, but each byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

### 15.3.1.1 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 15-3.

**Figure 15-3. START and STOP Conditions**

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due to an error), the interrupt pin becomes active and the data may be read from the **I<sup>2</sup>C Master Data (I2CMDR)** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, two bits in the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus; while two bits in the **I<sup>2</sup>C Slave Masked Interrupt Status (I2CSMIS)** register allow start and stop conditions to be promoted to controller interrupts (when interrupts are enabled).

### 15.3.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 15-4. After the START condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSA** register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/transmit formats are then possible within a single transfer.

**Figure 15-4. Complete Data Transfer with a 7-Bit Address**

The first seven bits of the first byte make up the slave address (see Figure 15-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the

master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

**Figure 15-5. R/S Bit in First Byte**

### 15.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 15-6).

**Figure 15-6. Data Validity During Bit Transfer on the I<sup>2</sup>C Bus**

### 15.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 965.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the **I<sup>2</sup>C Slave ACK Control (I2CSACKCTL)** register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the I<sup>2</sup>C clock is pulled low after the last data bit until this register is written with the indicated response.

### 15.3.1.5 Clock Low Timeout

The I<sup>2</sup>C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I<sup>2</sup>C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the **I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT)** register. Application can program the 8 most significant bits of the counter to reflect the acceptable cumulative low period in transaction. The count is loaded at the START condition and counts down on each falling edge of the internal

bus clock of the master. Note that the internal bus clock generated for this counter keeps running at the programmed I<sup>2</sup>C speed even if the SCL is held low on the bus. Upon reaching terminal count, the master state machine forces Abort on the bus by issuing a STOP condition at the instance of SCL and SDA release.

As an example, if an I<sup>2</sup>C module was operating at 100 kHz speed, programming the **I2CMCLKOCNT** register to 0xDA would result in a cumulative clock low period of 34.88 ms.

The CLKRIS bit in the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register is set when the clock timeout period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the CLKTO bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register is set; this bit is cleared when a STOP condition is sent or during the I<sup>2</sup>C master reset.. The status of the raw SDA and SCL signals are readable by software through the SDA and SCL bits in the **I<sup>2</sup>C Master Bus Monitor (I2CMBMON)** register to help determine the state of the remote slave.

If the slave holds the clock low continuously, the only solution is to interrupt the processor using the CLKRIS bit and resolve the condition at higher protocol levels by resetting both the master and the remote slave.

#### 15.3.1.6 Dual Address

The I<sup>2</sup>C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I<sup>2</sup>C slave provides an ACK on the bus if the address matches the OAR field in the **I2CSOAR** register. In dual address mode, the I<sup>2</sup>C slave provides an ACK on the bus if either the OAR field in the **I2CSOAR** register or the OAR2 field in the **I2CSOAR2** register is matched. The enable for dual address is programmable through the OAR2EN bit in the **I2CSOAR2** register and there is no disable on the legacy address.

The OAR2SEL bit in the **I2CSCSR** register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either legacy operation or no address match.

#### 15.3.1.7 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a '1' (High) on SDA while another master transmits a '0' (Low) switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

#### 15.3.1.8 High-Speed Operation

The Stellaris I<sup>2</sup>C peripheral has support for High-speed operation as both a master and slave. When operating as a master, the protocol is shown in Figure 15-7. The master is responsible for sending a master code byte in either Standard (100 Kbps) or Fast-mode (400 Kbps) before it begins transferring in High-speed mode. The master code byte must contain data in the form of 0000.1XXX and is used to tell the slave devices to prepare for a High-speed transfer. The master code byte should never be acknowledged by a slave since it is only used to indicate that the upcoming data is going to be transferred at a higher data rate. To send the master code byte, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with a value of 0x11. This places the I<sup>2</sup>C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command

bits, without setting the HS bit in the **I2CMCS** register. Again, setting the HS bit in the **I2CMCS** register is only necessary during the master code byte.

When operating as a High-speed slave, there is no additional software required.

**Figure 15-7. High-Speed Data Format**

**Note:** High-Speed mode is 3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines.

## 15.3.2 Available Speed Modes

The I<sup>2</sup>C bus can run in Standard mode (100 kbps), Fast mode (400 kbps), Fast mode plus (1 Mbps) or High-Speed mode (3.33 Mbps). The selected mode should match the speed of the other I<sup>2</sup>C devices on the bus.

### 15.3.2.1 Standard, Fast, and Fast Plus Modes

Standard, Fast, and Fast Plus modes are selected using a value in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode, 400 kbps for Fast mode, or 1 Mbps for Fast mode plus.

The I<sup>2</sup>C clock rate is determined by the parameters *CLK\_PRD*, *TIMER\_PRD*, *SCL\_LP*, and *SCL\_HP* where:

*CLK\_PRD* is the system clock period

*SCL\_LP* is the low phase of SCL (fixed at 6)

*SCL\_HP* is the high phase of SCL (fixed at 4)

*TIMER\_PRD* is the programmed value in the **I2CMTPR** register (see page 988).

The I<sup>2</sup>C clock period is calculated as follows:

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

For example:

$$CLK\_PRD = 50 \text{ ns}$$

$$TIMER\_PRD = 2$$

$$SCL\_LP = 6$$

$$SCL\_HP = 4$$

yields a SCL frequency of:

$$1/SCL\_PERIOD = 333 \text{ KHz}$$

Table 15-2 gives examples of the timer periods that should be used to generate Standard, Fast mode, and Fast mode plus SCL frequencies based on various system clock frequencies.

**Table 15-2. Examples of I<sup>2</sup>C Master Timer Period versus Speed Mode**

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 4 MHz        | 0x01         | 100 Kbps      | -            | -         | -            | -              |
| 6 MHz        | 0x02         | 100 Kbps      | -            | -         | -            | -              |
| 12.5 MHz     | 0x06         | 89 Kbps       | 0x01         | 312 Kbps  | -            | -              |
| 16.7 MHz     | 0x08         | 93 Kbps       | 0x02         | 278 Kbps  | -            | -              |
| 20 MHz       | 0x09         | 100 Kbps      | 0x02         | 333 Kbps  | -            | -              |
| 25 MHz       | 0x0C         | 96.2 Kbps     | 0x03         | 312 Kbps  | -            | -              |
| 33 MHz       | 0x10         | 97.1 Kbps     | 0x04         | 330 Kbps  | -            | -              |
| 40 MHz       | 0x13         | 100 Kbps      | 0x04         | 400 Kbps  | 0x01         | 1000 Kbps      |
| 50 MHz       | 0x18         | 100 Kbps      | 0x06         | 357 Kbps  | 0x02         | 833 Kbps       |
| 80 MHz       | 0x27         | 100 Kbps      | 0x09         | 400 Kbps  | 0x03         | 1000 Kbps      |

### 15.3.2.2 High-Speed Mode

High-Speed mode is configured by setting the HS bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register. High-Speed mode transmits data at a high bit rate with a 66.6%/33.3% duty cycle, but communication and arbitration are done at Standard, Fast mode, or Fast-mode plus speed, depending on which is selected by the user. When the HS bit in the **I2CMCS** register is set, current mode pull-ups are enabled.

The clock period can be selected using the equation above, but in this case, SCL\_LP=2 and SCL\_HP=1. So for example:

```
CLK_PRD = 25 ns
TIMER_PRD = 1
SCL_LP=2
SCL_HP=1
```

yields a SCL frequency of:

$$1/T = 3.33 \text{ Mhz}$$

Table 15-3 on page 968 gives examples of timer period and system clock in High-Speed mode.

**Table 15-3. Examples of I<sup>2</sup>C Master Timer Period in High-Speed Mode**

| System Clock | Timer Period | Transmission Mode |
|--------------|--------------|-------------------|
| 40 MHz       | 0x01         | 3.33 Mbps         |
| 50 MHz       | 0x02         | 2.77 Mbps         |
| 80 MHz       | 0x03         | 3.33 Mbps         |

### 15.3.3 Interrupts

The I<sup>2</sup>C can generate interrupts when the following conditions are observed:

- Master transaction completed
- Master arbitration lost
- Master transaction error

- Master bus timeout
- Slave transaction received
- Slave transaction requested
- Stop condition on bus detected
- Start condition on bus detected

The I<sup>2</sup>C master and I<sup>2</sup>C slave modules have separate interrupt signals. While both modules can generate interrupts for multiple conditions, only a single interrupt signal is sent to the interrupt controller.

#### 15.3.3.1 I<sup>2</sup>C Master Interrupts

The I<sup>2</sup>C master module generates an interrupt when a transaction completes (either transmit or receive), when arbitration is lost, or when an error occurs during a transaction. To enable the I<sup>2</sup>C master interrupt, software must set the IM bit in the **I<sup>2</sup>C Master Interrupt Mask (I2CMIMR)** register. When an interrupt condition is met, software must check the ERROR and ARBLST bits in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register to verify that an error didn't occur during the last transaction and to ensure that arbitration has not been lost. An error condition is asserted if the last transaction wasn't acknowledged by the slave. If an error is not detected and the master has not lost arbitration, the application can proceed with the transfer. The interrupt is cleared by writing a 1 to the IC bit in the **I<sup>2</sup>C Master Interrupt Clear (I2CMICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register.

#### 15.3.3.2 I<sup>2</sup>C Slave Interrupts

The slave module can generate an interrupt when data has been received or requested. This interrupt is enabled by setting the DATAIM bit in the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register. Software determines whether the module should write (transmit) or read (receive) data from the **I<sup>2</sup>C Slave Data (I2CSDR)** register, by checking the RREQ and TREQ bits of the **I<sup>2</sup>C Slave Control/Status (I2CSCSR)** register. If the slave module is in receive mode and the first byte of a transfer is received, the FBR bit is set along with the RREQ bit. The interrupt is cleared by setting the DATAIC bit in the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

In addition, the slave module can generate an interrupt when a start and stop condition is detected. These interrupts are enabled by setting the STARTIM and STOPIM bits of the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register and cleared by writing a 1 to the STOPIC and STARTIC bits of the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register.

#### 15.3.4 Loopback Operation

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and slave modules are tied together.

### **15.3.5 Command Sequence Flow Charts**

This section details the steps required to perform the various I<sup>2</sup>C transfer types in both master and slave mode.

#### **15.3.5.1 I<sup>2</sup>C Master Command Sequences**

The figures that follow show the command sequences available for the I<sup>2</sup>C master.

Figure 15-8. Master Single TRANSMIT

Figure 15-9. Master Single RECEIVE

Figure 15-11. Master RECEIVE with Repeated START

**Figure 15-12. Master RECEIVE with Repeated START after TRANSMIT with Repeated START**

**Figure 15-13. Master TRANSMIT with Repeated START after RECEIVE with Repeated START**

Figure 15-14. High Speed Mode Master Transmit

### 15.3.5.2 I<sup>2</sup>C Slave Command Sequences

Figure 15-15 on page 978 presents the command sequence available for the I<sup>2</sup>C slave.

**Figure 15-15. Slave Command Sequence**

## 15.4 Initialization and Configuration

The following example shows how to configure the I<sup>2</sup>C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I<sup>2</sup>C clock using the **RCGCI2C** register in the System Control module (see page 326).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 319). To find out which GPIO port to enable, refer to Table 22-5 on page 1314.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 644). To determine which GPIOs to configure, see Table 22-4 on page 1307.
4. Enable the I2CSDA pin for open-drain operation. See page 649.

5. Configure the PMCN fields in the **GPIOPCTL** register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 661 and Table 22-5 on page 1314.
6. Initialize the I<sup>2</sup>C Master by writing the **I2CMCR** register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:
 
$$\text{TPR} = (\text{System Clock} / (2 * (\text{SCL\_LP} + \text{SCL\_HP}) * \text{SCL\_CLK})) - 1;$$

$$\text{TPR} = (20\text{MHz} / (2 * (6+4) * 1000000)) - 1;$$

$$\text{TPR} = 9$$

Write the **I2CMTPR** register with the value of 0x0000.0009.
8. Specify the slave address of the master and that the next operation is a Transmit by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the **I2CMDR** register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

## 15.5 Register Map

Table 15-4 on page 980 lists the I<sup>2</sup>C registers. All addresses given are relative to the I<sup>2</sup>C base address:

- I<sup>2</sup>C 0: 0x4002.0000
- I<sup>2</sup>C 1: 0x4002.1000
- I<sup>2</sup>C 2: 0x4002.2000
- I<sup>2</sup>C 3: 0x4002.3000
- I<sup>2</sup>C 4: 0x400C.0000
- I<sup>2</sup>C 5: 0x400C.1000

Note that the I<sup>2</sup>C module clock must be enabled before the registers can be programmed (see page 326). There must be a delay of 3 system clocks after the I<sup>2</sup>C module clock is enabled before any I<sup>2</sup>C module registers are accessed.

The `hw_i2c.h` file in the StellarisWare® Driver Library uses a base address of 0x800 for the I<sup>2</sup>C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that StellarisWare uses an offset between 0x000 and 0x018 with the slave base address.

Table 15-4. Inter-Integrated Circuit (I<sup>2</sup>C) Interface Register Map

| Offset                                   | Name        | Type | Reset       | Description                        | See page |
|------------------------------------------|-------------|------|-------------|------------------------------------|----------|
| <b>I<sup>2</sup>C Master</b>             |             |      |             |                                    |          |
| 0x000                                    | I2CMSA      | R/W  | 0x0000.0000 | I2C Master Slave Address           | 981      |
| 0x004                                    | I2CMCS      | R/W  | 0x0000.0020 | I2C Master Control/Status          | 982      |
| 0x008                                    | I2CMDR      | R/W  | 0x0000.0000 | I2C Master Data                    | 987      |
| 0x00C                                    | I2CMTPR     | R/W  | 0x0000.0001 | I2C Master Timer Period            | 988      |
| 0x010                                    | I2CMIMR     | R/W  | 0x0000.0000 | I2C Master Interrupt Mask          | 989      |
| 0x014                                    | I2CMRIS     | RO   | 0x0000.0000 | I2C Master Raw Interrupt Status    | 990      |
| 0x018                                    | I2CMMIS     | RO   | 0x0000.0000 | I2C Master Masked Interrupt Status | 991      |
| 0x01C                                    | I2CMICR     | WO   | 0x0000.0000 | I2C Master Interrupt Clear         | 992      |
| 0x020                                    | I2CMCR      | R/W  | 0x0000.0000 | I2C Master Configuration           | 993      |
| 0x024                                    | I2CMCLKOCNT | R/W  | 0x0000.0000 | I2C Master Clock Low Timeout Count | 994      |
| 0x02C                                    | I2CMBMON    | RO   | 0x0000.0003 | I2C Master Bus Monitor             | 995      |
| <b>I<sup>2</sup>C Slave</b>              |             |      |             |                                    |          |
| 0x800                                    | I2CSOAR     | R/W  | 0x0000.0000 | I2C Slave Own Address              | 996      |

## 15.6 Register Descriptions (I<sup>2</sup>C Master)

The remainder of this section lists and describes the I<sup>2</sup>C master registers, in numerical order by address offset.

**Register 1: I<sup>2</sup>C Master Slave Address (I2CMSA), offset 0x000**

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

**I2C Master Slave Address (I2CMSA)**

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 I2C 2 base: 0x4002.2000  
 I2C 3 base: 0x4002.3000

**Register 2: I<sup>2</sup>C Master Control/Status (I2CMCS), offset 0x004**

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I<sup>2</sup>C bus controller. When written, the control register configures the I<sup>2</sup>C controller operation.

The START bit generates the START or REPEATED START condition. The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and this register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set, causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

a. An X in a table cell indicates the bit can be 0 or 1.

b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

### Register 3: I<sup>2</sup>C Master Data (I2CMDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state.

#### I2C Master Data (I2CMDR)

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000

**Register 4: I<sup>2</sup>C Master Timer Period (I2CMTPR), offset 0x00C**

This register is programmed to set the timer period for the SCL clock and assign the SCL clock to either standard or high-speed mode.

**I2C Master Timer Period (I2CMTPR)**

## Register 10: I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT), offset 0x024

This register contains the upper 8 bits of a 12-bit counter that can be used to keep the timeout limit for clock stretching by a remote slave. The lower four bits of the counter are not user visible.

**15.7 Register Descriptions (I<sup>2</sup>C Slave)**

The remainder of this section lists and describes the I<sup>2</sup>C slave registers, in numerical order by address offset.

**Register 12: I<sup>2</sup>C Slave Own Address (I2CSOAR), offset 0x800**

This register consists of seven address bits that identify the Stellaris I<sup>2</sup>C device on the I<sup>2</sup>C bus.

**I2C Slave Own Address (I2CSOAR)**

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 I2C 2 base: 0x4002.2000  
 I2C 3 base: 0x4002.3000  
 I2C 4 base: 0x400C.0000  
 I2C 5 base: 0x400C.1000  
 Offset 0x800  
 Type R/W, reset 0x0000.0000

## Register 13: I<sup>2</sup>C Slave Control/Status (I2CSCSR), offset 0x804

This register functions as a control register when written, and a status register when read.

### Read-Only Status Register

|           |          |      |            | 1 Enables the I <sup>2</sup> C slave operation.                                                                                                                                               |
|           |          |      |            | Once this bit has been set, it should not be set again unless it has been cleared by writing a 0 or by a reset, otherwise transfer failures may occur.                                        |

**Register 14: I<sup>2</sup>C Slave Data (I2CSDR), offset 0x808**

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Slave Transmit state, and the data received when in the Slave Receive state.

**I2C Slave Data (I2CSDR)**

I2C 0 base: 0x4002.0000

| 0 | The interface is set to Standard, Fast or Fast mode plus operation.                                                                                           |

## 16 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The Stellaris<sup>®</sup> LM4F231H5QR microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

## 16.1 Block Diagram

Figure 16-1. CAN Controller Block Diagram

## 16.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 644) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 661) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 623.

**Table 16-1. Controller Area Network Signals (64LQFP)**

| Pin Name | Pin Number     | Pin Mux / Pin Assignment      | Pin Type | Buffer Type <sup>a</sup> | Description            |
|----------|----------------|-------------------------------|----------|--------------------------|------------------------|
| CAN0Rx   | 28<br>58<br>59 | PF0 (3)<br>PB4 (8)<br>PE4 (8) | I        | TTL                      | CAN module 0 receive.  |
| CAN0Tx   | 31<br>57<br>60 | PF3 (3)<br>PB5 (8)<br>PE5 (8) | O        | TTL                      | CAN module 0 transmit. |
| CAN1Rx   | 17             | PA0 (8)                       | I        | TTL                      | CAN module 1 receive.  |
| CAN1Tx   | 18             | PA1 (8)                       | O        | TTL                      | CAN module 1 transmit. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 16.3 Functional Description

The Stellaris CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 16-2.

**Figure 16-2. CAN Data/Remote Frame**

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the Stellaris memory map, so the Stellaris CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. The message object memory cannot be directly accessed, so these two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

### 16.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 463). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 471). To find out which GPIO port to enable, refer to Table 22-4 on page 1307. Set the GPIO AFSEL bits for the appropriate pins (see page 644). Configure the PMCN fields in the **GPIOCTL** register to assign the CAN signals to the appropriate pins. See page 661 and Table 22-5 on page 1314.

Software initialization is started by setting the INIT bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While INIT is set, all message transfers to and from the CAN bus are stopped and the CANnTX signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the MSGVAL bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the INIT and CCE bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the INIT bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the MSGVAL bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the MSGVAL bit again to indicate that the message object is once again valid.

### 16.3.2 Operation

Two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to

queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the INIT bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the MNUM bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the MSK bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate TXRQST bit in the **CAN Transmission Request n (CANTXRQn)** register and the NEWDAT bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (MNUM) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the RMTEN bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the TXRQST bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The UMASK bit in the **CANIFnMCTL** register enables the MSK bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The MXTD bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

### 16.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's NEWDAT bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the TXRQST bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the TXIE bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the INTPND bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is

re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

### 16.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
  - Set the WRNRD bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the IDMASK, DIR, and MXTD of the message object into the **CAN IFn** registers using the MASK bit
  - Specify whether to transfer the ID, DIR, XTD, and MSGVAL of the message object into the interface registers using the ARB bit
  - Specify whether to transfer the control bits into the interface registers using the CONTROL bit
  - Specify whether to clear the INTPND bit in the **CANIFnMCTL** register using the CLRINTPND bit
  - Specify whether to clear the NEWDAT bit in the **CANNWDAn** register using the NEWDAT bit
  - Specify which bits to transfer using the DATAA and DATAB bits
2. In the **CANIFnMSK1** register, use the MSK[15:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[15:0] in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure ID[15:0] in the **CANIFnARB1** register for bits [15:0] of the message identifier and ID[12:0] in the **CANIFnARB2** register for bits [28:16] of the message identifier. Set the XTD bit to indicate an extended identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure ID[12:2] in the **CANIFnARB2** register for bits [10:0] of the message identifier. Clear the XTD bit to indicate a standard identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:

- Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the TXIE bit to enable the INTPND bit to be set after a successful transmission
  - Optionally set the RMTEN bit to enable the TXRQST bit to be set on the reception of a matching remote frame allowing automatic transmission
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame. Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register.
  8. Program the number of the message object to be transmitted in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register.
  9. When everything is properly configured, set the TXRQST bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the RMTEN bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

### 16.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the MSGVAL bit in the **CANIFnARB2** register nor the TXRQST bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the WRNRD, DATAA and DATAB bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1, CANIFnDA2, CANIFnDB1, and CANIFnDB2** registers, and then the number of the message object is written to the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the TXRQST bit in the **CANIFnMSKn** register.

To prevent the clearing of the TXRQST bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the NEWDAT and TXRQST bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, NEWDAT is cleared as soon as the new transmission has started.

### 16.3.6 Accepting Received Message Objects

When the arbitration and control field (the ID and XTD bits in the **CANIFnARB2** and the RMTEN and DLC[3:0] bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the UMASK bit in the **CANIFnMCTL** register. Each valid

message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

### 16.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The NEWDAT bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the NEWDAT bit is already set, the MSGST bit in the **CANIFnMCTL** register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the RXIE bit of the **CANIFnMCTL** register should be set. In this case, the INTPND bit of the same register is set, causing the **CANINT** register to point to the message object that just received a message. The TXRQST bit of this message object should be cleared to prevent the transmission of a remote frame.

### 16.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

**Table 16-2. Message Object Configurations**

| Configuration in <b>CANIFnMCTL</b>                                                                                                                                                                                                                                                                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 1 (set the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame to enable transmission)</li> <li>■ UMASK = 1 or 0</li> </ul>                                                                           | At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.                                                                                                                                                                                                                                                                                                                                                                                   |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 0 (ignore mask in the <b>CANIFnMSKn</b> register)</li> </ul>                                             | At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened.                                                                                                                                                                                                                                                                                                                                                                  |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the <b>CANIFnMSKn</b> register) for acceptance filtering)</li> </ul> | At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM, and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the Stellaris controller does not have readily available data. The software must fill the data and answer the frame manually. |

### 16.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

#### 16.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 1013 section, except that the WRNRD bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 1013 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 1013 section to program XTD and ID bits for the message identifier to be received; set the MSGVAL bit to indicate a valid message; and clear the DIR bit to specify receive.
5. In the **CANIFnMCTL** register:
  - Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the RXIE bit to enable the INTPND bit to be set after a successful reception
  - Clear the RMTEN bit to leave the TXRQST bit unchanged
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frameTake care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
6. Program the number of the message object to be received in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The UMASK bit in the **CANIFnMCTL** register enables the MSK bits in the **CANIFnMSKn** register to filter which frames are received. The MXTD bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

### 16.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the NEWDAT and INTPND bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The NEWDAT bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The MSGLST bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. MSGLST is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the TXRQST bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TXRQST bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

#### 16.3.11.1 Configuration of a FIFO Buffer

With the exception of the EOB bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see "Configuring a Receive Message Object" on page 1016). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The EOB bit of all message objects of a FIFO buffer except the last one must be cleared. The EOB bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

#### 16.3.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NEWDAT of the **CANIFnMCTL** register bit of this message object is set. By setting

NEWDAT while EOB is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the NEWDAT bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the NEWDAT bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

#### 16.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the TXRQST and CLRINTPND bits in the **CANIFnCMSK** register should be set such that the NEWDAT and INTPEND bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message is placed in the message object with the lowest message number for which the NEWDAT bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 16-3 on page 1019 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 16-3. Message Objects in a FIFO Buffer

### 16.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's INTPND bit in the **CANIFnMCTL** register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier INTID in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as 0x0000. If the value of the INTID field is different from 0, then an interrupt is pending. If the IE bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the INTID field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until IE is cleared, which disables interrupts from the CAN controller.

The INTID field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The SIE bit in the **CANCTL** register controls whether a change of the RXOK, TXOK, and LEC bits in the **CANSTS** register can cause an interrupt. The EIE bit in the **CANCTL** register controls whether a change of the BOFF and EWARN bits in the **CANSTS** register can cause an interrupt. The IE bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the IE bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the RXOK, TXOK, and LEC bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the INTID bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's INTPND bit at the same time by setting the CLRINTPND bit in the **CANIFnCMSK** register. Once the INTPND bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

### 16.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the TEST bit in the **CANCTL** register. Once in Test Mode, the TX[1:0], LBACK, SILENT and BASIC bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The RX bit in the **CANTST** register allows monitoring of the CANnRX signal. All **CANTST** register functions are disabled when the TEST bit is cleared.

#### 16.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the SILENT bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

### 16.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the CANnTX signal on to the CANnRX signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the LBACK bit in the **CANTST** register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the CANnRX signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the CANnTX signal.

### 16.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the CANnTX and CANnRX signals. In this mode, the CANnRX signal is disconnected from the CAN Controller and the CANnTX signal is held recessive. This mode is enabled by setting both the LBACK and SILENT bits in the **CANTST** register.

### 16.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the BUSY bit of the **CANIF1CRQ** register. The CANIF1 registers are locked while the BUSY bit is set. The BUSY bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the BUSY bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the BUSY bit in the **CANIF1CRQ** register while the CANIF1 registers are locked. If the CPU has cleared the BUSY bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the BUSY bit of the **CANIF2CRQ** register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the **CANIFnCMSK** registers are not evaluated. The message number of the **CANIFnCRQ** registers is also not evaluated. In the **CANIF2MCTL** register, the NEWDAT and MSGST bits retain their function, the DLC[3:0] field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the BASIC bit in the **CANTST** register.

### 16.3.13.5 Transmit Control

Software can directly override control of the CANnTX signal in four different ways.

- CANnTX is controlled by the CAN Controller
- The sample point is driven on the CANnTX signal to monitor the bit timing
- CANnTX drives a low value
- CANnTX drives a high value

The last two functions, combined with the readable CAN receive pin CANnRX, can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the TX[1:0] field in the **CANTST** register. The three test functions for the CANnTX signal interfere with all CAN protocol functions. TX[1:0] must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

### 16.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

### 16.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 16-4 on page 1023): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 16-3 on page 1023). The length of the time quantum ( $t_q$ ), which is the basic time unit of the bit time, is defined by the CAN controller's input clock ( $f_{sys}$ ) and the Baud Rate Prescaler (BRP):

$$t_q = \text{BRP} / f_{sys}$$

The  $f_{sys}$  input clock is the system clock frequency as configured by the **RCC** or **RCC2** registers (see page 249 or page 256).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of Sync and the Sync is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 16-4. CAN Bit Time

Table 16-3. CAN Protocol Ranges<sup>a</sup>

| Parameter | Range          | Remark                                                                                                              |
|-----------|----------------|---------------------------------------------------------------------------------------------------------------------|
| BRP       | [1 .. 64]      | Defines the length of the time quantum $t_q$ . The <b>CANBRPE</b> register can be used to extend the range to 1024. |
| Sync      | 1 $t_q$        | Fixed length, synchronization of bus input to system clock                                                          |
| Prop      | [1 .. 8] $t_q$ | Compensates for the physical delay times                                                                            |
| Phase1    | [1 .. 8] $t_q$ | May be lengthened temporarily by synchronization                                                                    |
| Phase2    | [1 .. 8] $t_q$ | May be shortened temporarily by synchronization                                                                     |
| SJW       | [1 .. 4] $t_q$ | May not be longer than either Phase Buffer Segment                                                                  |

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 16-4 shows the relationship between the **CANBIT** register values and the parameters.

Table 16-4. CANBIT Register Values

| CANBIT Register Field | Setting           |
|-----------------------|-------------------|
| TSEG2                 | Phase2 - 1        |
| TSEG1                 | Prop + Phase1 - 1 |
| SJW                   | SJW - 1           |
| BRP                   | BRP               |

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than  $2 t_q$ ; the CAN's IPT is  $0 t_q$ . Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

### 16.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

Sync is  $1 t_q$  long (fixed), which leaves  $(\text{bit time} - \text{Prop} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, that is,  $\text{Phase2} = \text{Phase1}$ , else  $\text{Phase2} = \text{Phase1} + 1$ .

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of  $[0..2] t_q$ .

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- $df$  = Maximum tolerance of oscillator frequency
- $f_{osc}$  = Actual oscillator frequency
- $f_{nom}$  = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(\text{Phase\_seg1}, \text{Phase\_seg2}) \min}{2 \times (13 \times t_{bit} - \text{Phase\_Seg2})}$$

$$df_{\max} = 2 \times df \times f_{nom}$$

where:

- Phase1 and Phase2 are from Table 16-3 on page 1023
- $t_{bit}$  = Bit Time
- $df_{\max}$  = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

### 16.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

$$\text{bit time} = 1 \mu\text{s} = n * t_q = 5 * t_q$$

$$t_q = 200 \text{ ns}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 200\text{E-9} * 25\text{E6} = 5$$

$$t_{\text{Sync}} = 1 * t_q = 200 \text{ ns}$$

\\fixed at 1 time quanta

delay of bus driver 50 ns

delay of receiver circuit 30 ns

delay of bus line (40m) 220 ns

$$t_{\text{Prop}} 400 \text{ ns} = 2 * t_q$$

\\400 is next integer multiple of  $t_q$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Tseg1}} + t_{\text{Tseg2}} = 5 * t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Prop}} + t_{\text{Phase 1}} + t_{\text{Phase 2}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = \text{bit time} - t_{\text{Sync}} - t_{\text{Prop}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = (5 * t_q) - (1 * t_q) - (2 * t_q)$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = 2 * t_q$$

$$t_{\text{Phase1}} = 1 * t_q$$

$$t_{\text{Phase2}} = 1 * t_q$$

\\tPhase2 = tPhase1

$$tTSeg1 = tProp + tPhase1$$

$$tTSeg1 = (2 * t_q) + (1 * t_q)$$

$$tTSeg1 = 3 * t_q$$

$$tTSeg2 = tPhase2$$

$$tTSeg2 = (\text{Information Processing Time} + 1) * t_q$$

$$tTSeg2 = 1 * t_q \quad \text{\textbackslash\textbackslash Assumes IPT=0}$$

$$tSJW = 1 * t_q \quad \text{\textbackslash\textbackslash Least of 4, Phase1 and Phase2}$$

In the above example, the bit field values for the **CANBIT** register are:

|       |                                           |
|-------|-------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 1-1<br>= 0                |
| TSEG1 | = TSeg1 -1<br>= 3-1<br>= 2                |
| SJW   | = SJW -1<br>= 1-1<br>= 0                  |
| BRP   | = Baud rate prescaler - 1<br>= 5-1<br>= 4 |

The final value programmed into the **CANBIT** register = 0x0204.

### 16.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

$$\text{bit time} = 10 \mu\text{s} = n * t_q = 10 * t_q$$

$$t_q = 1 \mu\text{s}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 1\text{E-6} * 50\text{E6} = 50$$

$$tSync = 1 * t_q = 1 \mu\text{s} \quad \text{\textbackslash\textbackslash fixed at 1 time quanta}$$

$$\text{delay of bus driver } 200 \text{ ns}$$

$$\text{delay of receiver circuit } 80 \text{ ns}$$

$$\text{delay of bus line (40m) } 220 \text{ ns}$$

$$tProp 1 \mu\text{s} = 1 * t_q \quad \text{\textbackslash\textbackslash } 1 \mu\text{s} \text{ is next integer multiple of } t_q$$

$$\text{bit time} = tSync + tTSeg1 + tTSeg2 = 10 * t_q$$

$$\text{bit time} = tSync + tProp + tPhase 1 + tPhase2$$

$$tPhase 1 + tPhase2 = \text{bit time} - tSync - tProp$$

$$tPhase 1 + tPhase2 = (10 * t_q) - (1 * t_q) - (1 * t_q)$$

$$tPhase 1 + tPhase2 = 8 * t_q$$

$$tPhase1 = 4 * t_q$$

$$tPhase2 = 4 * t_q \quad \text{\textbackslash\textbackslash } tPhase1 = tPhase2$$

|       |                                            |
|-------|--------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 4-1<br>= 3                 |
| TSEG1 | = TSeg1 -1<br>= 5-1<br>= 4                 |
| SJW   | = SJW -1<br>= 4-1<br>= 3                   |
| BRP   | = Baud rate prescaler - 1<br>= 50-1<br>=49 |

## 16.4 Register Map

- CAN0: 0x4004.0000
- CAN1: 0x4004.1000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 329). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

## 16.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in

the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

**Register 1: CAN Control (CANCTL), offset 0x000**

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing INIT. If the device goes bus-off, it sets INIT, stopping all bus activities. Once INIT has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 \* 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after INIT is cleared, each time a sequence of 11 High bits has been monitored, a BITERROR0 code is written to the **CANSTS** register (the LEC field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

**CAN Control (CANCTL)**

**Register 2: CAN Status (CANSTS), offset 0x004**

**Important:** This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

**CAN Status (CANSTS)**

CAN0 base: 0x4004.0000  
CAN1 base: 0x4004.1000  
Offset 0x004  
Type R/W, reset 0x0000.0000

When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |  | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0). | 0x5 | Bit 0 Error |  | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1). |  | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus. | 0x6 | CRC Error |  | The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data. | 0x7 | No Event |  | When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field. |
| Value     | Description                                                                                                                                                                                                                                                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).                                                                                                                                                    |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1).                                                                                                                                                   |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

**Register 3: CAN Error Counter (CANERR), offset 0x008**

This register contains the error counter values, which can be used to analyze the cause of an error.

**CAN Error Counter (CANERR)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x008

Type RO, reset 0x0000.0000

**Register 4: CAN Bit Timing (CANBIT), offset 0x00C**

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the CCE and INIT bits in the **CANCTL** register. See “Bit Time and Bit Rate” on page 1022 for more information.

The bit time quanta is defined by the BRP field.                                                                                                                                                                 |
| 11:8      | TSEG1    | R/W  | 0x3    | Time Segment Before Sample Point<br>0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for Phase1 (see Figure 16-4 on page 1023). The bit time quanta is defined by the BRP field.                                                                                                                                                                |
| 7:6       | SJW      | R/W  | 0x0    | (Re)Synchronization Jump Width<br>0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of TSEG2 or TSEG1 by the value in SJW. So the reset value of 0 adjusts the length by 1 bit time quanta.                                                                                                                       |
| 5:0       | BRP      | R/W  | 0x1    | Baud Rate Prescaler<br>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.<br>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>BRP defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).<br>The <b>CANBRPE</b> register can be used to further divide the bit time. |

## Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the INTID field is not 0x0000 (the default) and the IE bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the INTID field is cleared by reading the **CANSTS** register, or until the IE bit in the **CANCTL** register is cleared.

**Note:** Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

**Register 6: CAN Test (CANTST), offset 0x014**

This register is used for self-test and external pin access. It is write-enabled by setting the TEST bit in the **CANCTL** register. Different test functions may be combined, however, CAN transfers are affected if the TX bits in this register are not zero.

**CAN Test (CANTST)**

In basic mode, software should use the <b>CANIF1</b> registers as the transmit buffer and use the <b>CANIF2</b> registers as the receive buffer. |
| 1:0       | reserved | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |                                                                                                                                                                         |

**Register 7: CAN Baud Rate Prescaler Extension (CANBRPE), offset 0x018**

This register is used to further divide the bit time set with the BRP bit in the **CANBIT** register. It is write-enabled by setting the CCE bit in the **CANCTL** register.

**CAN Baud Rate Prescaler Extension (CANBRPE)**

| 3:0       | BRPE     | R/W  | 0x0        | Baud Rate Prescaler Extension<br>0x00-0x0F: Extend the BRP bit in the <b>CANBIT</b> register to values up to 1023. The actual interpretation by the hardware is one more than the value programmed by BRPE (MSBs) and BRP (LSBs). |

**Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020****Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the **CANIF1MCTL** register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN\_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

**CAN IFn Command Request (CANIFnCRQ)**

**Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024****Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

**CAN IFn Command Mask (CANIFnCMSK)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x024

Type R/W, reset 0x0000.0000

| 1         | If WRNRD is clear, the new data status is cleared in the message buffer. Note the value of this bit that is transferred to the <b>CANIFnMCTL</b> register always reflects the status of the bits before clearing.<br>If WRNRD is set, a transmission is requested. Note that when this bit is set, the TXRQST bit in the <b>CANIFnMCTL</b> register is ignored. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |       |             |   |                                                                                                                                                                                                         |   |                                                                                                                                                                                                                                                                                                                                                                 |

**Register 12: CAN IF1 Mask 1 (CANIF1MSK1), offset 0x028****Register 13: CAN IF2 Mask 1 (CANIF2MSK1), offset 0x088**

The mask information provided in this register accompanies the data (**CANIFnDAn**), arbitration information (**CANIFnARBn**), and control information (**CANIFnMCTL**) to the message object in the message RAM. The mask is used with the ID bit in the **CANIFnARBn** register for acceptance filtering. Additional mask information is contained in the **CANIFnMSK2** register.

**CAN IFn Mask 1 (CANIFnMSK1)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x028

When the TXRQST bit in the <b>CANIFnMCTL</b> register is set, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TXRQST bit of this message object is set (if RMTEN=1). |
| Value     | Description                                                                                                                                                                                                                                               |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |             |   |                                                                                                                                                                                                                                                     |   |                                                                                                                                                                                                                                                           |
| 0         | Receive. When the TXRQST bit in the <b>CANIFnMCTL</b> register is set, a remote frame with the identifier of this message object is received. On reception of a data frame with matching identifier, that message is stored in this message object.       |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |             |   |                                                                                                                                                                                                                                                     |   |                                                                                                                                                                                                                                                           |

**Register 22: CAN IF1 Data A1 (CANIF1DA1), offset 0x03C**

**Register 23: CAN IF1 Data A2 (CANIF1DA2), offset 0x040**

**Register 24: CAN IF1 Data B1 (CANIF1DB1), offset 0x044**

**Register 25: CAN IF1 Data B2 (CANIF1DB2), offset 0x048**

**Register 26: CAN IF2 Data A1 (CANIF2DA1), offset 0x09C**

**Register 27: CAN IF2 Data A2 (CANIF2DA2), offset 0x0A0**

**Register 28: CAN IF2 Data B1 (CANIF2DB1), offset 0x0A4**

**Register 29: CAN IF2 Data B2 (CANIF2DB2), offset 0x0A8**

These registers contain the data to be sent or that has been received. In a CAN data frame, data byte 0 is the first byte to be transmitted or received and data byte 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte is transmitted first.

**Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100****Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104**

The **CANTXRQ1** and **CANTXRQ2** registers hold the TXRQST bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The TXRQST bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the TXRQST bits of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the TXRQST bits of the second 16 message objects.

**CAN Transmission Request n (CANTXRQn)**

**Register 32: CAN New Data 1 (CANNWDA1), offset 0x120****Register 33: CAN New Data 2 (CANNWDA2), offset 0x124**

The **CANNWDA1** and **CANNWDA2** registers hold the NEWDAT bits of the 32 message objects. By reading these bits, the CPU can check which message object has its data portion updated. The NEWDAT bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a data frame, or (3) the message handler state machine after a successful transmission.

The **CANNWDA1** register contains the NEWDAT bits of the first 16 message objects in the message RAM; the **CANNWDA2** register contains the NEWDAT bits of the second 16 message objects.

**Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140****Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144**

The **CANMSG1INT** and **CANMSG2INT** registers hold the INTPND bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The INTPND bit of a specific message object can be changed through two sources: (1) the CPU via the **CANIFnMCTL** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CANINT** register.

The **CANMSG1INT** register contains the INTPND bits of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the INTPND bits of the second 16 message objects.

## 17 Universal Serial Bus (USB) Controller

The Stellaris® USB controller operates as a full-speed or low-speed function controller during point-to-point communications with USB Host, Device, or OTG functions. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. 16 endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus 14 endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing.  $\mu$ DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device start-up. The controller complies with OTG standard's session request protocol (SRP) and host negotiation protocol (HNP).

The Stellaris USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation with integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop and valid ID detection and interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive for up to three IN endpoints and three OUT endpoints
  - Channel requests asserted when FIFO contains required amount of data

## 17.1 Block Diagram

Figure 17-1. USB Module Block Diagram

## 17.2 Signal Description

The following table lists the external signals of the USB controller and describes the function of each. Some USB controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these USB signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 644) should be set to choose the USB function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPTCL)** register (page 661) to assign the USB signal to the specified GPIO port pin. The USB0VBUS and USB0ID signals are configured by clearing the appropriate DEN bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 623. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Note:** When used in OTG mode, USB0VBUS and USB0ID do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the DEVMODOTG and DEVMOD bits in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the USB0VBUS and USB0ID inputs to fixed levels internally, freeing the PB0 and PB1 pins for GPIO use. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

Table 17-1. USB Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                              |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------------------------------------------|
| USB0DM   | 43         | PD4                      | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0. |

Table 17-1. USB Signals (64LQFP) (continued)

| Pin Name | Pin Number          | Pin Mux / Pin Assignment                 | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                   |

| USB0EPEN | 5<br>14<br>33<br>63 | PF4 (8)<br>PC6 (8)<br>PG4 (8)<br>PD2 (8) | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                              |
| USB0ID   | 45                  | PB0                                      | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| USB0PFLT | 13<br>32<br>64      | PC7 (8)<br>PG5 (8)<br>PD3 (8)            | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                     |
| USB0VBUS | 46                  | PB1                                      | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                            |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 17.3 Functional Description

The Stellaris USB controller provides full OTG negotiation by supporting both the session request protocol (SRP) and the host negotiation protocol (HNP). The session request protocol allows devices on the B side of a cable to request the A side device turn on VBUS. The host negotiation protocol is used after the initial session request protocol has powered the bus and provides a method to determine which end of the cable will act as the Host controller. When the device is connected to non-OTG peripherals or devices, the controller can detect which cable end was used and provides a register to indicate if the controller should act as the Host or the Device controller. This indication and the mode of operation are handled automatically by the USB controller. This auto-detection allows the system to use a single A/B connector instead of having both A and B connectors in the system and supports full OTG negotiations with other OTG devices.

In addition, the USB controller provides support for connecting to non-OTG peripherals or Host controllers. The USB controller can be configured to act as either a dedicated Host or Device, in which case, the USB0VBUS and USB0ID signals can be used as GPIOs. However, when the USB controller is acting as a self-powered Device, a GPIO input or analog comparator input must be connected to VBUS and configured to generate an interrupt when the VBUS level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

**Note:** When the USB module is in operation, MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 30 MHz.

### 17.3.1 Operation as a Device

This section describes the Stellaris USB controller's actions when it is being used as a USB Device. Before the USB controller's operating mode is changed from Device to Host or Host to Device, software must reset the USB controller by setting the USB0 bit in the **Software Reset Control 2 (SRCR2)** register (see page 461). IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of Start of Frame (SOF) are all described.

When in Device mode, IN transactions are controlled by an endpoint's transmit interface and use the transmit endpoint registers for the given endpoint. OUT transactions are handled with an endpoint's receive interface and use the receive endpoint registers for the given endpoint.

When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint for a USB Device. However, in most cases the USB Device should use the dedicated control endpoint on the USB controller's endpoint 0.

### 17.3.1.1 Endpoints

When operating as a Device, the USB controller provides two dedicated control endpoints (IN and OUT) and 14 configurable endpoints (7 IN and 7 OUT) that can be used for communications with a Host controller. The endpoint number and direction associated with an endpoint is directly related to its register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface.

Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.

The remaining 14 endpoints can be configured as control, bulk, interrupt, or isochronous endpoints. They should be treated as 7 configurable IN and 7 configurable OUT endpoints. The endpoint pairs are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair could be a bulk endpoint, while the IN portion of that endpoint pair could be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

### 17.3.1.2 IN Transactions as a Device

When operating as a USB Device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the 7 configurable IN endpoints are determined by the **USB Transmit FIFO Start Address (USBTXFIFOADD)** register. The maximum size of a data packet that may be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the **USB Maximum Transmit Data Endpoint n (USBTXMAXPn)** register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

**Note:** The maximum packet size set for any endpoint must not exceed the FIFO size. The **USBTXMAXPn** register should not be written to while data is in the FIFO as unexpected results may occur.

### Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the **USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ)** register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the **USB Transmit Control and Status Endpoint n Low (USBTXCSSLn)** register must be set. If the AUTOSET bit in the **USB Transmit Control and Status Endpoint n High (USBTXCSRHn)** register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

### Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the **USBTXCSSLn** register must be set. If the AUTOSET bit in the **USBTXCSRHn** register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the **USBTXCSSLn** register at this point indicates how many packets may be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the **USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

#### 17.3.1.3 OUT Transactions as a Device

When in Device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the 7 configurable OUT endpoints are determined by the **USB Receive FIFO Start Address (USBRXFIFOADD)** register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the **USB Maximum Receive Data Endpoint n (USBRXMAXPn)** register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

**Note:** In all cases, the maximum packet size must not exceed the FIFO size.

### Single-Packet Buffering

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the **USB Receive Control and Status Endpoint n Low (USBRXCSSLn)** register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet

has been unloaded, the RXRDY bit must be cleared in order to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the **USB Receive Control and Status Endpoint n High (USBXCSRHN)** register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

#### ***Double-Packet Buffering***

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the **USBXCSRLn** register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

**Note:** The FULL bit in **USBXCSRLn** is not set when the first packet is received. It is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the **USBXCSRHN** register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the **USB Receive Double Packet Buffer Disable (USBXDPKTBUDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

### **17.3.1.4 Scheduling**

The Device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The Stellaris USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the Device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

### **17.3.1.5 Additional Actions**

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

#### ***Stalled Control Transfer***

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the **USB Control and Status Endpoint 0 Low (USBCSRL0)** register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller

when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what should have been the last packet.

3. The Host sends more than **USBRXMAXPn** bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

#### **Zero Length OUT Data Packets**

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the Device request has been transferred.

However, if the Host sends a zero-length OUT data packet before the entire length of Device request has been transferred, it is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the **USBCSRL0** register.

#### **Setting the Device Address**

When a Host is attempting to enumerate the USB Device, it requests that the Device change its address from zero to some other value. The address is changed by writing the value that the Host requested to the **USB Device Functional Address (USBFADDR)** register. However, care should be taken when writing to **USBFADDR** to avoid changing the address before the transaction is complete. This register should only be set after the SET\_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the Device has left the STATUS phase. In the case of a SET\_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the Device has responded to the IN request, the **USBFADDR** register should be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

**Note:** If the **USBFADDR** register is set to the new value as soon as the Device receives the OUT transaction with the SET\_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the Device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the Device.

#### **17.3.1.6 Device Mode SUSPEND**

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the **USB Interrupt Enable (USBIE)** register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the **USB Power (USBPOWER)** register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling.

To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state.

#### 17.3.1.7 Start-of-Frame

When the USB controller is operating in Device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the **USB Frame Value (USBFRAME)** register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the **USBFRAME** register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

#### 17.3.1.8 USB RESET

When the USB controller is in Device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the **USBFADDR** register.
- Clears the **USB Endpoint Index (USBEPIDX)** register.
- Flushes all endpoint FIFOs.
- Clears all control/status registers.
- Enables all endpoint interrupts.
- Generates a RESET interrupt.

When the application software driving the USB controller receives a RESET interrupt, any open pipes are closed and the USB controller waits for bus enumeration to begin.

#### 17.3.1.9 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the **SOFTCONN** bit of the **USBPOWER** register. When the **SOFTCONN** bit is set, the PHY is placed in its normal mode, and the **USB0DP/USB0DM** lines of the USB bus are enabled. At the same time, the USB controller is placed into a state, in which it does not respond to any USB signaling except a USB RESET.

When the **SOFTCONN** bit is cleared, the PHY is put into non-driving mode, **USB0DP** and **USB0DM** are tristated, and the USB controller appears to other devices on the USB bus as if it has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the **SOFTCONN** bit has been set. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the **SOFTCONN** bit has been set, the USB controller can be disconnected by clearing this bit.

**Note:** The USB controller does not generate an interrupt when the Device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

### 17.3.2 Operation as a Host

When the Stellaris USB controller is operating in Host mode, it can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Before the USB controller's operating mode is changed from Host to Device or

Device to Host, software must reset the USB controller by setting the USB0 bit in the **Software Reset Control 2 (SRCR2)** register (see page 461). Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, isochronous, and interrupt transactions are supported. This section describes the USB controller's actions when it is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in Device mode, the FIFOs for endpoints should take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint to communicate with a Device. However, in most cases the USB controller should use the dedicated control endpoint to communicate with a Device's endpoint 0.

### 17.3.2.1 Endpoints

The endpoint registers are used to control the USB endpoint interfaces which communicate with Device(s) that are connected. The endpoints consist of a dedicated control IN endpoint, a dedicated control OUT endpoint, 7 configurable OUT endpoints, and 7 configurable IN endpoints.

The dedicated control interface can only be used for control transactions to endpoint 0 of Devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of Devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, interrupt, or isochronous Device endpoints.

These USB interfaces can be used to simultaneously schedule as many as 7 independent OUT and 7 independent IN transactions to any endpoints on any Device. The IN and OUT controls are paired in three sets of registers. However, they can be configured to communicate with different types of endpoints and different endpoints on Devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a Device's bulk OUT endpoint 1, while the IN portion is communicating with a Device's interrupt IN endpoint 2.

Before accessing any Device, whether for point-to-point communications or for communications via a hub, the relevant **USB Receive Functional Address Endpoint n (USBRXFUNCADDRn)** or **USB Transmit Functional Address Endpoint n (USBTXFUNCADDRn)** registers must be set for each receive or transmit endpoint to record the address of the Device being accessed.

The USB controller also supports connections to Devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

### 17.3.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in Device mode except that the transaction first must be initiated by setting the REQPKT bit in the **USBCSRL0** register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target Device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the **USBCSRL0** register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the **USBXCSRHn** register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in **USBXCSRHn** causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. The AUTOCL and AUTORQ bits can be used with  $\mu$ DMA accesses to perform complete bulk transfers without main processor intervention. When the RXRDY bit is cleared, the controller sends an acknowledge to the Device. When there is a known number of packets to be transferred, the **USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNTn)** register associated with the endpoint should be configured to the number of packets to be transferred. The USB controller decrements the value in the **USBRQPKTCOUNTn** register following each request. When the **USBRQPKTCOUNTn** value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, **USBRQPKTCOUNTn** should be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the **USBRXMAXPn** register) such as may occur at the end of a bulk transfer.

If the Device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target Device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the **USBCSRL0** register. If the target Device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target Device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the **USBCSRL0** register.

### 17.3.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in Device mode. The TXRDY bit in the **USBTXCSRLn** register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the **USBTXCSRHn** register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO. Furthermore, AUTOSET can be used with the  $\mu$ DMA controller to perform complete bulk transfers without software intervention.

If the target Device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target Device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the **USBTXCSRLn** register. If the target Device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target Device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the **USBTXCSRLn** register.

### 17.3.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every

255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a Device is not responding. Isochronous endpoints can be scheduled from every frame to every  $2^{16}$  frames, in powers of 2.

The USB controller maintains a frame counter. If the target Device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target Device is a low-speed device, a *K* state is transmitted on the bus to act as a *keep-alive* to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An isochronous or interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt or isochronous transaction occurs per endpoint every *n* frames, where *n* is the interval set via the **USB Host Transmit Interval Endpoint *n* (USBTXINTERVAL<sub>n</sub>)** or **USB Host Receive Interval Endpoint *n* (USBRXINTERVAL<sub>n</sub>)** register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target Device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process ensures that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target Device before the endpoint times out.

### 17.3.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed Device is connected to the USB controller via a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding **USB Receive Hub Address Endpoint *n* (USBRXHUBADDR<sub>n</sub>)** and **USB Receive Hub Port Endpoint *n* (USBRXHUBPORT<sub>n</sub>)** or the **USB Transmit Hub Address Endpoint *n* (USBTXHUBADDR<sub>n</sub>)** and **USB Transmit Hub Port Endpoint *n* (USBTXHUBPORT<sub>n</sub>)** registers. In addition, the speed at which the Device operates (full or low) must be recorded in the **USB Type Endpoint 0 (USBTYP0)** (endpoint 0), **USB Host Configure Transmit Type Endpoint *n* (USBTXTYPE<sub>n</sub>)**, or **USB Host Configure Receive Type Endpoint *n* (USBRXTYPE<sub>n</sub>)** registers for each endpoint that is accessed by the Device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB Devices. To maximize the number of Devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to Device functions must be made following the completion of any on-going transactions on the endpoints affected.

### 17.3.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target Device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

#### 17.3.2.7 Host SUSPEND

If the SUSPEND bit in the **USBPOWER** register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20 ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

#### 17.3.2.8 USB RESET

If the RESET bit in the **USBPOWER** register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20 ms to ensure correct resetting of the target Device. After the CPU has cleared the bit, the USB Host controller starts its frame counter and transaction scheduler.

#### 17.3.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the **USB Device Control (USBDEVCTL)** register, enabling the USB controller to wait for a Device to be connected. When a Device is detected, a connect interrupt is generated. The speed of the Device that has been connected can be determined by reading the **USBDEVCTL** register where the FSDEV bit is set for a full-speed Device, and the LSDEV bit is set for a low-speed Device. The USB controller must generate a RESET to the Device, and then the USB Host controller can begin Device enumeration. If the Device is disconnected while a session is in progress, a disconnect interrupt is generated.

### 17.3.3 OTG Mode

To conserve power, the USB On-The-Go (OTG) supplement allows VBUS to only be powered up when required and to be turned off when the bus is not in use. VBUS is always supplied by the A device on the bus. The USB OTG controller determines whether it is the A device or the B device by sampling the ID input from the PHY. This signal is pulled Low when an A-type plug is sensed (signifying that the USB OTG controller should act as the A device) but taken High when a B-type plug is sensed (signifying that the USB controller is a B device). Note that when switching between OTG A and OTG B, the USB controller retains all register contents.

#### 17.3.3.1 Starting a Session

When the USB OTG controller is ready to start a session, the SESSION bit must be set in the **USBDEVCTL** register. The USB OTG controller then enables ID pin sensing. The ID input is either taken Low if an A-type connection is detected or High if a B-type connection is detected. The DEV bit in the **USBDEVCTL** register is also set to indicate whether the USB OTG controller has adopted the role of the A device or the B device. The USB OTG controller also provides an interrupt to indicate that ID pin sensing has completed and the mode value in the **USBDEVCTL** register is valid. This interrupt is enabled in the **USBIDVIM** register, and the status is checked in the **USBIDVISC** register. As soon as the USB controller has detected that it is on the A side of the cable, it must enable VBUS power within 100ms or the USB controller reverts to Device mode.

If the USB OTG controller is the A device, then the USB OTG controller enters Host mode (the A device is always the default Host), turns on VBUS, and waits for VBUS to go above the VBUS Valid threshold, as indicated by the VBUS bit in the **USBDEVCTL** register going to 0x3. The USB OTG controller then waits for a peripheral to be connected. When a peripheral is detected, a Connect interrupt is signaled and either the FSDEV or LSDEV bit in the **USBDEVCTL** register is set, depending whether a full-speed or a low-speed peripheral is detected. The USB controller then issues a RESET

to the connected Device. The SESSION bit in the **USBDEVCTL** register can be cleared to end a session. The USB OTG controller also automatically ends the session if babble is detected or if VBUS drops below session valid.

**Note:** The USB OTG controller may not remain in Host mode when connected to high-current devices. Some devices draw enough current to momentarily drop VBUS below the VBUS-valid level causing the controller to drop out of Host mode. The only way to get back into Host mode is to allow VBUS to go below the Session End level. In this situation, the device is causing VBUS to drop repeatedly and pull VBUS back low the next time VBUS is enabled.

In addition, the USB OTG controller may not remain in Host mode when a device is told that it can start using its active configuration. At this point the device starts drawing more current and can also drop VBUS below VBUS valid.

If the USB OTG controller is the B device, then the USB OTG controller requests a session using the session request protocol defined in the USB On-The-Go supplement, that is, it first discharges VBUS. Then when VBUS has gone below the Session End threshold (VBUS bit in the **USBDEVCTL** register goes to 0x0) and the line state has been a single-ended zero for > 2 ms, the USB OTG controller pulses the data line, then pulses VBUS. At the end of the session, the SESSION bit is cleared either by the USB OTG controller or by the application software. The USB OTG controller then causes the PHY to switch out the pull-up resistor on D+, signaling the A device to end the session.

### 17.3.3.2 Detecting Activity

When the other device of the OTG setup wishes to start a session, it either raises VBUS above the Session Valid threshold if it is the A device, or if it is the B device, it pulses the data line then pulses VBUS. Depending on which of these actions happens, the USB controller can determine whether it is the A device or the B device in the current setup and act accordingly. If VBUS is raised above the Session Valid threshold, then the USB controller is the B device. The USB controller sets the SESSION bit in the **USBDEVCTL** register. When RESET signaling is detected on the bus, a RESET interrupt is signaled, which is interpreted as the start of a session.

The USB controller is in Device mode as the B device is the default mode. At the end of the session, the A device turns off the power to VBUS. When VBUS drops below the Session Valid threshold, the USB controller detects this drop and clears the SESSION bit to indicate that the session has ended, causing a disconnect interrupt to be signaled. If data line and VBUS pulsing is detected, then the USB controller is the A device. The controller generates a SESSION REQUEST interrupt to indicate that the B device is requesting a session. The SESSION bit in the **USBDEVCTL** register must be set to start a session.

### 17.3.3.3 Host Negotiation

When the USB controller is the A device, ID is Low, and the controller automatically enters Host mode when a session starts. When the USB controller is the B device, ID is High, and the controller automatically enters Device mode when a session starts. However, software can request that the USB controller become the Host by setting the HOSTREQ bit in the **USBDEVCTL** register. This bit can be set either at the same time as requesting a Session Start by setting the SESSION bit in the **USBDEVCTL** register or at any time after a session has started. When the USB controller next enters SUSPEND mode and if the HOSTREQ bit remains set, the controller enters Host mode and begins host negotiation (as specified in the USB On-The-Go supplement) by causing the PHY to disconnect the pull-up resistor on the D+ line, causing the A device to switch to Device mode and connect its own pull-up resistor. When the USB controller detects this, a Connect interrupt is generated and the RESET bit in the **USBPOWER** register is set to begin resetting the A device. The

USB controller begins this reset sequence automatically to ensure that RESET is started as required within 1 ms of the A device connecting its pull-up resistor. The main processor should wait at least 20 ms, then clear the RESET bit and enumerate the A device.

When the USB OTG controller B device has finished using the bus, the USB controller goes into SUSPEND mode by setting the SUSPEND bit in the **USBPOWER** register. The A device detects this and either terminates the session or reverts to Host mode. If the A device is USB OTG controller, it generates a Disconnect interrupt.

### 17.3.4 DMA Operation

The USB peripheral provides an interface connected to the  $\mu$ DMA controller with separate channels for 3 transmit endpoints and 3 receive endpoints. Software selects which endpoints to service with the  $\mu$ DMA channels using the **USB DMA Select (USBDMASEL)** register. The  $\mu$ DMA operation of the USB is enabled through the **USBTXCSRHn** and **USBRXCSRHn** registers, for the TX and RX channels respectively. When  $\mu$ DMA operation is enabled, the USB asserts a  $\mu$ DMA request on the enabled receive or transmit channel when the associated FIFO can transfer data. When either FIFO can transfer data, the burst request for that channel is asserted. The  $\mu$ DMA channel must be configured to operate in Basic mode, and the size of the  $\mu$ DMA transfer must be restricted to whole multiples of the size of the USB FIFO. Both read and write transfers of the USB FIFOs using  $\mu$ DMA must be configured in this manner. For example, if the USB endpoint is configured with a FIFO size of 64 bytes, the  $\mu$ DMA channel can be used to transfer 64 bytes to or from the endpoint FIFO. If the number of bytes to transfer is less than 64, then a programmed I/O method must be used to copy the data to or from the FIFO.

If the DMAMOD bit in the **USBTXCSRHn/USBRXCSRHn** register is clear, an interrupt is generated after every packet is transferred, but the  $\mu$ DMA continues transferring data. If the DMAMOD bit is set, an interrupt is generated only when the entire  $\mu$ DMA transfer is complete. The interrupt occurs on the USB interrupt vector. Therefore, if interrupts are used for USB operation and the  $\mu$ DMA is enabled, the USB interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

Care must be taken when using the  $\mu$ DMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of value of the MAXLOAD field in the **USBRXCSRHn** register. The RXRDY bit is cleared as follows.

**Table 17-2. Remainder (MAXLOAD/4)**

| Value | Description        |
|-------|--------------------|
| 0     | MAXLOAD = 64 bytes |
| 1     | MAXLOAD = 61 bytes |
| 2     | MAXLOAD = 62 bytes |
| 3     | MAXLOAD = 63 bytes |

**Table 17-3. Actual Bytes Read**

| Value | Description |
|-------|-------------|
| 0     | MAXLOAD     |
| 1     | MAXLOAD+3   |
| 2     | MAXLOAD+2   |
| 3     | MAXLOAD+1   |

**Table 17-4. Packet Sizes That Clear RXRDY**

| Value | Description                              |
|-------|------------------------------------------|
| 0     | MAXLOAD, MAXLOAD-1, MAXLOAD-2, MAXLOAD-3 |
| 1     | MAXLOAD                                  |
| 2     | MAXLOAD, MAXLOAD-1                       |
| 3     | MAXLOAD, MAXLOAD-1, MAXLOAD-2            |

To enable DMA operation for the endpoint receive channel, the DMAEN bit of the **USBXCSRHn** register should be set. To enable DMA operation for the endpoint transmit channel, the DMAEN bit of the **USBTXCSRHn** register must be set.

See “Micro Direct Memory Access (μDMA)” on page 559 for more details about programming the μDMA controller.

## 17.4 Initialization and Configuration

To use the USB Controller, the peripheral clock must be enabled via the **RCGCUSB** register (see page 328). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register in the System Control module (see page 319). To find out which GPIO port to enable, refer to Table 22-4 on page 1307. Configure the PMCN fields in the **GPIOPCTL** register to assign the USB signals to the appropriate pins (see page 661 and Table 22-5 on page 1314).

The initial configuration in all cases requires that the processor enable the USB controller and USB controller's physical layer interface (PHY) before setting any registers. The next step is to enable the USB PLL so that the correct clocking is provided to the PHY. To ensure that voltage is not supplied to the bus incorrectly, the external power control signal, USB0EPEN, should be negated on start up by configuring the USB0EPEN and USB0PFLT pins to be controlled by the USB controller and not exhibit their default GPIO behavior.

**Note:** When used in OTG mode, USB0VBUS and USB0ID do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the DEVMODOTG and DEVMOD bits in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the USB0VBUS and USB0ID inputs to fixed levels internally, freeing the PB0 and PB1 pins for GPIO use. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

### 17.4.1 Pin Configuration

When using the Device controller portion of the USB controller in a system that also provides Host functionality, the power to VBUS must be disabled to allow the external Host controller to supply power. Usually, the USB0EPEN signal is used to control the external regulator and should be negated to avoid having two devices driving the USB0VBUS power pin on the USB connector.

When the USB controller is acting as a Host, it is in control of two signals that are attached to an external voltage supply that provides power to VBUS. The Host controller uses the USB0EPEN signal to enable or disable power to the USB0VBUS pin on the USB connector. An input pin, USB0PFLT, provides feedback when there has been a power fault on VBUS. The USB0PFLT signal can be configured to either automatically negate the USB0EPEN signal to disable power, and/or it can generate an interrupt to the interrupt controller to allow software to handle the power fault condition. The polarity and actions related to both USB0EPEN and USB0PFLT are fully configurable in the USB

controller. The controller also provides interrupts on Device insertion and removal to allow the Host controller code to respond to these external events.

## 17.4.2 Endpoint Configuration

To start communication in Host or Device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a Device. In Device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because it is a fixed-function, fixed-FIFO-size endpoint. In Device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In Device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, interrupt or isochronous mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. Isochronous endpoints can have packets with up to 1023 bytes per packet. In either mode, the maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 2 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a Device, the USB Device controller's soft connect must be enabled when the Device is ready to start communications, indicating to the Host controller that the Device is ready to start the enumeration process. If operating as a Host controller, the Device soft connect must be disabled and power must be provided to VBUS via the USB0EPEN signal.

## 17.5 Register Map

Table 17-5 on page 1074 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 328). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

**Table 17-5. Universal Serial Bus (USB) Controller Register Map**

| Offset | Name     | Type | Reset  | Description                   | See page |
|--------|----------|------|--------|-------------------------------|----------|
| 0x000  | USBFADDR | R/W  | 0x00   | USB Device Functional Address | 1081     |
| 0x001  | USBPOWER | R/W  | 0x20   | USB Power                     | 1082     |
| 0x002  | USBTXIS  | RO   | 0x0000 | USB Transmit Interrupt Status | 1085     |
| 0x004  | USBRXIS  | RO   | 0x0000 | USB Receive Interrupt Status  | 1087     |
| 0x006  | USBTXIE  | R/W  | 0xFFFF | USB Transmit Interrupt Enable | 1088     |
| 0x008  | USBRXIE  | R/W  | 0xFFFE | USB Receive Interrupt Enable  | 1090     |
| 0x00A  | USBIS    | RO   | 0x00   | USB General Interrupt Status  | 1091     |

**Table 17-5. Universal Serial Bus (USB) Controller Register Map (continued)**

| Offset | Name           | Type | Reset       | Description                                            | See page |
|--------|----------------|------|-------------|--------------------------------------------------------|----------|
| 0x00B  | USBIE          | R/W  | 0x06        | USB Interrupt Enable                                   | 1094     |
| 0x00C  | USBFRAME       | RO   | 0x0000      | USB Frame Value                                        | 1097     |
| 0x00E  | USBEPIDX       | R/W  | 0x00        | USB Endpoint Index                                     | 1098     |
| 0x00F  | USBTEST        | R/W  | 0x00        | USB Test Mode                                          | 1099     |
| 0x020  | USBFIFO0       | R/W  | 0x0000.0000 | USB FIFO Endpoint 0                                    | 1101     |
| 0x024  | USBFIFO1       | R/W  | 0x0000.0000 | USB FIFO Endpoint 1                                    | 1101     |

## 17.6 Register Descriptions

The LM4F231H5QR USB controller has On-The-Go (OTG) capabilities as specified in the USB0 bit field in the **DC6** register (see page 449).

**OTG B /  
Device**

This icon indicates that the register is used in OTG B or Device mode. Some registers are used for both Host and Device mode and may have different bit definitions depending on the mode.

**OTG A /  
Host**

This icon indicates that the register is used in OTG A or Host mode. Some registers are used for both Host and Device mode and may have different bit definitions depending on the mode. The USB controller is in OTG B or Device mode upon reset, so the reset values shown for these registers apply to the Device mode definition.

**OTG**

This icon indicates that the register is used for OTG-specific functions such as ID detection and negotiation. Once OTG negotiation is complete, then the USB controller registers are used according to their Host or Device mode meanings depending on whether the OTG negotiations made the USB controller OTG A (Host) or OTG B (Device).

OTG B /  
Device

Register 1: USB Device Functional Address (USBFADDR), offset 0x000

**USBFADDR** is an 8-bit register that contains the 7-bit address of the Device part of the transaction. When the USB controller is being used in Device mode (the HOST bit in the **USBDEVCTL** register is clear), this register must be written with the address received through a SET\_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

**Important:** See the section called “Setting the Device Address” on page 1065 for special considerations when writing this register.

## Register 2: USB Power (USBPOWER), offset 0x001

OTG A /  
Host

**USBPOWER** is an 8-bit register used for controlling SUSPEND and RESUME signaling and some basic operational aspects of the USB controller.

OTG B /

**Register 3: USB Transmit Interrupt Status (USBTXIS), offset 0x002****Important:** This register is read-sensitive. See the register description for details.**OTG A /  
Host**

**USBTXIS** is a 16-bit read-only register that indicates which interrupts are currently active for endpoint 0 and the transmit endpoints 1–7. The meaning of the EPn bits in this register is based on the mode of the device. The EP1 through EP7 bits always indicate that the USB controller is sending data; however, in Host mode, the bits refer to OUT endpoints; while in Device mode, the bits refer to IN endpoints. The EP0 bit is special in Host and Device modes and indicates that either a control IN or control OUT endpoint has generated an interrupt.

**OTG B /  
Device**

**Note:** Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

**Register 5: USB Transmit Interrupt Enable (USBTXIE), offset 0x006****OTG A /  
Host**

**USBTXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBTXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBTXIS** register is set. When a bit is cleared, the interrupt in the **USBTXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

**OTG B /  
Device**

USB Transmit Interrupt Enable (USBTXIE)

**Register 6: USB Receive Interrupt Enable (USBRXIE), offset 0x008****OTG A /  
Host**

**USBXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBXIS** register is set. When a bit is cleared, the interrupt in the **USBXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

**Register 8: USB Interrupt Enable (USBIE), offset 0x00B**

OTG A /  
Host

**USBIE** is an 8-bit register that provides interrupt enable bits for each of the interrupts in **USBIS**. At reset interrupts 1 and 2 are enabled in Device mode.

OTG B /  
Device

**Register 11: USB Test Mode (USBTEST), offset 0x00F**

**OTG A /  
Host**

**USBTEST** is an 8-bit register that is primarily used to put the USB controller into one of the four test modes for operation described in the *USB 2.0 Specification*, in response to a SET FEATURE: USBTESTMODE command. This register is not used in normal operation.

**OTG B /  
Device**

**Note:** Only one of these bits should be set at any time.

**OTG A / Host Mode****USB Test Mode (USBTEST)**

Base 0x4005.0000  
Offset 0x00F  
Type R/W, reset 0x00

| Bit/Field | Name   | Type | Reset | Description     |
|-----------|--------|------|-------|-----------------|
| 7         | FORCEH | R/W  | 0     | Force Host Mode |

**Value Description**

- 1 Forces the USB controller to enter Host mode when the SESSION bit is set, regardless of whether the USB controller is connected to any peripheral. The state of the USB0DP and USB0DM signals is ignored. The USB controller then remains in Host mode until the SESSION bit is cleared, even if a Device is disconnected. If the FORCEH bit remains set, the USB controller re-enters Host mode the next time the SESSION bit is set.

- 0 No effect.

While in this mode, status of the bus connection may be read using the DEV bit of the **USBDEVCTL** register. The operating speed is determined from the FORCEFS bit.

**Register 12: USB FIFO Endpoint 0 (USBFIFO0), offset 0x020**

**Register 13: USB FIFO Endpoint 1 (USBFIFO1), offset 0x024**

**Register 14: USB FIFO Endpoint 2 (USBFIFO2), offset 0x028**

**Register 15: USB FIFO Endpoint 3 (USBFIFO3), offset 0x02C**

**Register 16: USB FIFO Endpoint 4 (USBFIFO4), offset 0x030**

**Register 17: USB FIFO Endpoint 5 (USBFIFO5), offset 0x034**

**Register 18: USB FIFO Endpoint 6 (USBFIFO6), offset 0x038**

**Register 19: USB FIFO Endpoint 7 (USBFIFO7), offset 0x03C**

**Important:** This register is read-sensitive. See the register description for details.

**OTG A /  
Host**

These 32-bit registers provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

**OTG B /  
Device**

Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of accesses is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, halfword- or word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering (see the section called “Single-Packet Buffering” on page 1063). Burst writing of multiple packets is not supported as flags must be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–7, the associated FIFO is completely flushed.

**Register 20: USB Device Control (USBDEVCTL), offset 0x060****OTG A /  
Host**

**USBDEVCTL** is an 8-bit register used for controlling and monitoring the USB VBUS line. If the PHY is suspended, no PHY clock is received and the VBUS is not sampled. In addition, in Host mode, **USBDEVCTL** provides the status information for the current operating mode (Host or Device) of the USB controller. If the USB controller is in Host mode, this register also indicates if a full- or low-speed Device has been connected.

**USBTXHUBPORT<sub>n</sub>** is an 8-bit read/write register that, like **USBTXHUBADDR<sub>n</sub>**, only must be written when a full- or low-speed Device is connected to transmit endpoint EP<sub>n</sub> via a USB 2.0 hub. This register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** **USBTXHUBPORT0** is used for both receive and transmit for endpoint 0.

**Register 80: USB Maximum Transmit Data Endpoint 7 (USBTXMAXP7), offset 0x170**

**OTG A /  
Host**

The **USBTXMAXP<sub>n</sub>** 16-bit register defines the maximum amount of data that can be transferred through the transmit endpoint in a single operation.

**OTG B /  
Device**

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO must be completely flushed (using the FLUSH bit in **USBTXCSRL<sub>n</sub>**) after writing the new value to this register.

**Note:** **USBTXMAXP<sub>n</sub>** must be set to an even number of bytes for proper interrupt generation in  $\mu$ DMA Basic Mode.

## Register 82: USB Control and Status Endpoint 0 High (USBCSRH0), offset 0x103

OTG A /  
Host

USBSR0H is an 8-bit register that provides control and status bits for endpoint 0.

OTG B /  
Device

### OTG A / Host Mode

### Register 83: USB Receive Byte Count Endpoint 0 (USBCOUNT0), offset 0x108

OTG A /  
Host

**USBCOUNT0** is an 8-bit read-only register that indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the RXRDY bit is set.

**Register 85: USB NAK Limit (USBNAKLMT), offset 0x10B****OTG A /  
Host**

**USBNAKLMT** is an 8-bit register that sets the number of frames after which endpoint 0 should time out on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their **USBTXINTERVALn** and **USBRXINTERVALn** registers.)

The number of frames selected is  $2^{(m-1)}$  (where  $m$  is the value set in the register, with valid values of 2–16). If the Host receives NAK responses from the target for more frames than the number represented by the limit set in this register, the endpoint is halted.

**Note:** A value of 0 or 1 disables the NAK timeout function.

|-----------|-------|------|-------|-------------|
| 7         | NAKTO | R/W  | 0     | NAK Timeout |

Value Description

0 No timeout.

1 *Bulk endpoints only:* Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the **USBTXINTERVALn** register. Software must clear this bit to allow the endpoint to continue.

| Bit/Field | Name    | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Value Description

0 The TXRDY bit must be set manually.

1 Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in **USBTXMAXPn**) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Register 106: USB Maximum Receive Data Endpoint 7 (USBRXMAXP7), offset 0x174**

**OTG A /  
Host**

The **USBRXMAXP<sub>n</sub>** is a 16-bit register which defines the maximum amount of data that can be transferred through the selected receive endpoint in a single operation.

**OTG B /  
Device**

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operations.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the receive endpoint, and must not exceed half the FIFO size if double-buffering is required.

**Note:** **USBRXMAXP<sub>n</sub>** must be set to an even number of bytes for proper interrupt generation in  $\mu$ DMA Basic mode.

**Register 120: USB Receive Control and Status Endpoint 7 High (USBXCSRH7), offset 0x177**

**OTG A /  
Host**

**USBXCSRHn** is an 8-bit register that provides additional control and status bits for transfers through the currently selected receive endpoint.

**OTG B /  
Device**

Host

OTG B /  
Device

**Note:** The value returned changes as the FIFO is unloaded and is only valid while the RXRDY bit in the **USBXCSSLn** register is set.

**USBXCOUNTn** is a 16-bit read-only register that holds the number of data bytes in the packet currently in line to be read from the receive FIFO. If the packet is transmitted as multiple bulk packets, the number given is for the combined packet.

**OTG A /  
Host**

**USBTXINTERVAL<sub>n</sub>** is an 8-bit register that, for interrupt and isochronous transfers, defines the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The **USBTXINTERVAL<sub>n</sub>** register value defines a number of frames, as follows:

| Transfer Type | Speed                   | Valid values (m) | Interpretation                                                                            |
|---------------|-------------------------|------------------|-------------------------------------------------------------------------------------------|
| Interrupt     | Low-Speed or Full-Speed | 0x01 – 0xFF      | The polling interval is $m$ frames.                                                       |
| Isochronous   | Full-Speed              | 0x01 – 0x10      | The polling interval is $2^{(m-1)}$ frames.                                               |
| Bulk          | Full-Speed              | 0x02 – 0x10      | The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function. |

Host**

**USBRXINTERVAL<sub>n</sub>** is an 8-bit register that, for interrupt and isochronous transfers, defines the polling interval for the currently selected receive endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The **USBRXINTERVAL<sub>n</sub>** register value defines a number of frames, as follows:

| Transfer Type | Speed                   | Valid values (m) | Interpretation                                                                            |
|---------------|-------------------------|------------------|-------------------------------------------------------------------------------------------|
| Interrupt     | Low-Speed or Full-Speed | 0x01 – 0xFF      | The polling interval is $m$ frames.                                                       |
| Isochronous   | Full-Speed              | 0x01 – 0x10      | The polling interval is $2^{(m-1)}$ frames.                                               |
| Bulk          | Full-Speed              | 0x02 – 0x10      | The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function. |

#### USB Host Receive Polling Interval Endpoint n (USBRXINTERVAL<sub>n</sub>)

**Register 156: USB Request Packet Count in Block Transfer Endpoint 1 (USBRQPKTCOUNT1), offset 0x304**

**Register 157: USB Request Packet Count in Block Transfer Endpoint 2 (USBRQPKTCOUNT2), offset 0x308**

**Register 158: USB Request Packet Count in Block Transfer Endpoint 3 (USBRQPKTCOUNT3), offset 0x30C**

**Register 159: USB Request Packet Count in Block Transfer Endpoint 4 (USBRQPKTCOUNT4), offset 0x310**

**Register 160: USB Request Packet Count in Block Transfer Endpoint 5 (USBRQPKTCOUNT5), offset 0x314**

**Register 161: USB Request Packet Count in Block Transfer Endpoint 6 (USBRQPKTCOUNT6), offset 0x318**

**Register 162: USB Request Packet Count in Block Transfer Endpoint 7 (USBRQPKTCOUNT7), offset 0x31C**

**OTG A /  
Host**

This 16-bit read/write register is used in Host mode to specify the number of packets that are to be transferred in a block transfer of one or more bulk packets to receive endpoint n. The USB controller uses the value recorded in this register to determine the number of requests to issue where the AUTORQ bit in the **USBRXCSRHn** register has been set. See “IN Transactions as a Host” on page 1068.

**Note:** Multiple packets combined into a single bulk packet within the FIFO count as one packet.

**Register 165: USB External Power Control (USBEPD), offset 0x400****OTG A /  
Host**

This 32-bit register specifies the function of the two-pin external power interface (USB0EPEN and USB0PFLT). The assertion of the power fault input may generate an automatic action, as controlled by the hardware configuration registers. The automatic action is necessary because the fault condition may require a response faster than one provided by firmware.

Value Description

1 A Power Fault status has been detected.

0 An interrupt has not occurred.

This bit is cleared by writing a 1 to the PF bit in the **USBEPICISC** register.

Register 167: USB External Power Control Interrupt Mask (USBEPICIM), offset 0x408

OTG A /  
Host

This 32-bit register specifies the interrupt mask of the two-pin external power interface.

USB External Power Control Interrupt Mask (USBEPICIM)

### Value Description

- 1 The PF bits in the **USBEPICRIS** and **USBEPICIM** registers are set, providing an interrupt to the interrupt controller.
- 0 No interrupt has occurred or the interrupt is masked.

This bit is cleared by writing a 1. Clearing this bit also clears the PF bit in the **USBEPICRIS** register.

Register 169: USB Device RESUME Raw Interrupt Status (USBDRRIS), offset 0x410

OTG A /  
Host

The **USBDRRIS** 32-bit register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

OTG B /  
Device

|           |          |      |            | This bit is cleared by writing a 1 to the RESUME bit in the <b>USBDRISC</b> register.                                                                                                         |

**Register 170: USB Device RESUME Interrupt Mask (USBDIM), offset 0x414****OTG A /  
Host**

The **USBDIM** 32-bit register is the masked interrupt status register. On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit sets the mask, preventing the interrupt from being signaled to the interrupt controller. Clearing a bit clears the corresponding mask, enabling the interrupt to be sent to the interrupt controller.

**OTG B /

| 31:1      | reserved | RO   | 0x00  | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | RESUME   | R/W  | 0     | RESUME Interrupt Mask                                                                                                                                                                         |

**Value Description**

- 1 The raw interrupt signal from a detected RESUME is sent to the interrupt controller. This bit should only be set when a SUSPEND has been detected (the SUSPEND bit in the **USBIS** register is set).
- 0 A detected RESUME does not affect the interrupt status.

## Register 171: USB Device RESUME Interrupt Status and Clear (USBDRISC), offset 0x418

OTG A /  
Host

The **USBDRISC** 32-bit register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

### Value Description

- |   |                                                                                                                                   |
|---|-----------------------------------------------------------------------------------------------------------------------------------|
| 1 | The RESUME bits in the <b>USBDRRIS</b> and <b>USBDRCIM</b> registers are set, providing an interrupt to the interrupt controller. |
| 0 | No interrupt has occurred or the interrupt is masked.                                                                             |

This bit is cleared by writing a 1. Clearing this bit also clears the RESUME bit in the **USBDRCRIS** register.

## Register 172: USB General-Purpose Control and Status (USBGPCS), offset 0x41C

OTG A /  
Host

OTG B /  
Device

**USBGPCS** provides the state of the internal ID signal.

**Note:** When used in OTG mode, USB0VBUS and USB0ID do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the DEVMOD0TG and DEVMOD bits in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the USB0VBUS and USB0ID inputs to fixed levels internally, freeing the PB0 and PB1 pins for GPIO use. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

**Register 173: USB VBUS Droop Control (USBVDC), offset 0x430**

**OTG A /  
Host**

This 32-bit register enables a controlled masking of VBUS to compensate for any in-rush current by a Device that is connected to the Host controller. The in-rush current can cause VBUS to droop, causing the USB controller's behavior to be unexpected. The USB Host controller allows VBUS to fall lower than the VBUS Valid level (4.75 V) but not below AValid (2.0 V) for 65 microseconds without signaling a VBUSERR interrupt in the controller. Without this, any glitch on VBUS would force the USB Host controller to remove power from VBUS and then re-enumerate the Device.

### Value Description

- |   |                                                                                                                                |
|---|--------------------------------------------------------------------------------------------------------------------------------|
| 1 | The VD bits in the <b>USBVDCRIS</b> and <b>USBVDCIM</b> registers are set, providing an interrupt to the interrupt controller. |
| 0 | No interrupt has occurred or the interrupt is masked.                                                                          |

This bit is cleared by writing a 1. Clearing this bit also clears the VD bit in the **USBVDCRIS** register.

## Register 177: USB ID Valid Detect Raw Interrupt Status (USBIDVRIS), offset 0x444

**OTG**

This 32-bit register specifies whether the unmasked interrupt status of the ID value is valid.

## 18 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

**Note:** Not all comparators have the option to drive an output pin. See “Signal Description” on page 1175 for more information.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The Stellaris<sup>®</sup> LM4F231H5QR microcontroller provides two independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

## 18.1 Block Diagram

Figure 18-1. Analog Comparator Module Block Diagram

## 18.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 644) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 661) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 623.

Table 18-1. Analog Comparators Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                         |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------|
| C0+      | 14         | PC6                      | I        | Analog                   | Analog comparator 0 positive input. |

Table 18-1. Analog Comparators Signals (64LQFP) (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                         |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------|
| C1-      | 16         | PC4                      | I        | Analog                   | Analog comparator 1 negative input. |
| C1o      | 29         | PF1 (9)                  | O        | TTL                      | Analog comparator 1 output.         |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 18.3 Functional Description

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$VIN- < VIN+, VOUT = 1$

$VIN- > VIN+, VOUT = 0$

As shown in Figure 18-2 on page 1176, the input source for VIN- is an external input, Cn-, where n is the analog comparator number. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference, V<sub>IREF</sub>.

Figure 18-2. Structure of Comparator Unit

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

Typically, the comparator output is used internally to generate an interrupt as controlled by the ISEN bit in the **ACCTL** register. The output may also be used to drive one of the external pins (C0o, C1o, or C2o), or generate an analog-to-digital converter (ADC) trigger.

**Important:** The ASRCP bits in the **ACCTL** register must be set before using the analog comparators.

### 18.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 18-3 on page 1177. The internal reference is controlled by a single configuration register (**ACREFCTL**).

**Figure 18-3. Comparator Internal Reference Structure**

**Note:** In the figure above, N\*R represents a multiple of the R value that produces the results specified in Table 18-2 on page 1177.

The internal reference can be programmed in one of two modes (low range or high range) depending on the RNG bit in the **ACREFCTL** register. When RNG is clear, the internal reference is in high-range mode, and when RNG is set the internal reference is in low-range mode.

In each range, the internal reference,  $V_{IREF}$ , has 16 pre-programmed thresholds or step values. The threshold to be used to compare the external input voltage against is selected using the VREF field in the **ACREFCTL** register.

In the high-range mode, the  $V_{IREF}$  threshold voltages start at the ideal high-range starting voltage of  $V_{DDA}/4.2$  and increase in ideal constant voltage steps of  $V_{DDA}/29.4$ .

In the low-range mode, the  $V_{IREF}$  threshold voltages start at 0 V and increase in ideal constant voltage steps of  $V_{DDA}/22.12$ . The ideal  $V_{IREF}$  step voltages for each mode and their dependence on the RNG and VREF fields are summarized in Table 18-2.

**Table 18-2. Internal Reference Voltage and ACREFCTL Field Values**

| ACREFCTL Register |               | Output Reference Voltage Based on VREF Field Value                                                                                                                                                                                                                                                                                                                                     |
|-------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EN Bit Value      | RNG Bit Value |                                                                                                                                                                                                                                                                                                                                                                                        |
| EN=0              | RNG=X         | 0 V (GND) for any value of VREF. It is recommended that RNG=1 and VREF=0 to minimize noise on the reference ground.                                                                                                                                                                                                                                                                    |
| EN=1              | RNG=0         | $V_{IREF}$ High Range: 16 voltage threshold values indexed by VREF = 0x0 .. 0xF<br>Ideal starting voltage (VREF=0): $V_{DDA} / 4.2$<br>Ideal step size: $V_{DDA} / 29.4$<br>Ideal $V_{IREF}$ threshold values: $V_{IREF}(VREF) = V_{DDA} / 4.2 + VREF * (V_{DDA} / 29.4)$ , for VREF = 0x0 .. 0xF<br>For minimum and maximum $V_{IREF}$ threshold values, see Table 18-3 on page 1178. |
|                   | RNG=1         | $V_{IREF}$ Low Range: 16 voltage threshold values indexed by VREF = 0x0 .. 0xF<br>Ideal starting voltage (VREF=0): 0 V<br>Ideal step size: $V_{DDA} / 22.12$<br>Ideal $V_{IREF}$ threshold values: $V_{IREF}(VREF) = VREF * (V_{DDA} / 22.12)$ , for VREF = 0x0 .. 0xF<br>For minimum and maximum $V_{IREF}$ threshold values, see Table 18-4 on page 1178.                            |

Note that the values shown in Table 18-2 are the ideal values of the  $V_{IREF}$  thresholds. These values actually vary between minimum and maximum values for each threshold step, depending on process and temperature. The minimum and maximum values for each step are given by:

- $V_{IREF}(VREF) [Min] = \text{Ideal } V_{IREF}(VREF) - (\text{Ideal Step size} - 2 \text{ mV}) / 2$
- $V_{IREF}(VREF) [Max] = \text{Ideal } V_{IREF}(VREF) + (\text{Ideal Step size} - 2 \text{ mV}) / 2$

Examples of minimum and maximum  $V_{IREF}$  values for  $V_{DDA} = 3.3V$  for high and low ranges, are shown in Table 18-3 and Table 18-4. Note that these examples are only valid for  $V_{DDA} = 3.3V$ ; values scale up and down with  $V_{DDA}$ .

**Table 18-3. Analog Comparator Voltage Reference Characteristics,  $V_{DDA} = 3.3V$ , EN= 1, and RNG = 0**

| VREF Value | $V_{IREF}$ Min | Ideal $V_{IREF}$ | $V_{IREF}$ Max | Unit |
|------------|----------------|------------------|----------------|------|
| 0x0        | 0.731          | 0.786            | 0.841          | V    |

## 18.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0000.0001 to the **RCGCACMP** register in the System Control module (see page 331).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 319). To find out which GPIO ports to enable, refer to Table 22-5 on page 1314.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 22-4 on page 1307.
4. Configure the PMCN fields in the **GPIOCTL** register to assign the analog comparator output signals to the appropriate pins (see page 661 and Table 22-5 on page 1314).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTLn** register with the value of 0x0000.040C.
7. Delay for 10  $\mu$ s.
8. Read the comparator output value by reading the **ACSTATn** register's OVAL value.

Change the level of the comparator negative input signal C- to see the OVAL value change.

## 18.5 Register Map

Table 18-5 on page 1179 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 331). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

**Table 18-5. Analog Comparators Register Map**

| Offset | Name     | Type  | Reset       | Description                                 | See page |

Clearing this bit also clears the IN0 bit in the <b>ACRIS</b> register.</p> |

## Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004

This register provides a summary of the interrupt status (raw) of the comparators. The bits in this register must be enabled to generate interrupts using the **ACINTEN** register.

**Register 3: Analog Comparator Interrupt Enable (ACINTEN), offset 0x008**

This register provides the interrupt enable for the comparators.

**Analog Comparator Interrupt Enable (ACINTEN)**

## Register 4: Analog Comparator Reference Voltage Control (ACREFCTL), offset 0x010

This register specifies whether the resistor ladder is powered on as well as the range and tap.

### Analog Comparator Reference Voltage Control (ACREFCTL)

## 19 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The Stellaris® microcontroller contains two PWM modules, each with four PWM generator blocks and a control block, for a total of 16 PWM outputs. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that share the same timer and frequency and can either be programmed with independent actions or as a single pair of complementary signals with dead-band delays inserted. The output signals, `pwmA'` and `pwmB'`, of the PWM generation blocks are managed by the output control block before being passed to the device pins as `MnPWM0` and `MnPWM1` or `MnPWM2` and `MnPWM3`, and so on.

Each Stellaris PWM module provides a great deal of flexibility and can generate simple PWM signals, such as those required by a simple charge pump as well as paired PWM signals with dead-band delays, such as those required by a half-H bridge driver. Three generator blocks can also generate the full six channels of gate controls required by a 3-phase inverter bridge.

Each PWM generator block has the following features:

- Three fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled, for a total of six inputs
- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified

- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Extended PWM synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

## **19.1 Block Diagram**

Figure 19-1 on page 1191 provides the Stellaris PWM module diagram and Figure 19-2 on page 1191 provides a more detailed diagram of a Stellaris PWM generator. The LM4F231H5QR controller contains two PWM modules, each with four generator blocks that generate eight independent PWM signals or four paired PWM signals with dead-band delays inserted.

## 19.2 Signal Description

The following table lists the external signals of the PWM modules and describes the function of each. The PWM controller signals are alternate functions for some GPIO signals and default to be

GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these PWM signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 644) should be set to choose the PWM function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 661) to assign the PWM signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 623.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 19.3 Functional Description

### 19.3.1 PWM Timer

The timer in each PWM generator runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse. In the figures in this chapter, these signals are labelled "dir," "zero," and "load."

### 19.3.2 PWM Comparators

Each PWM generator has two comparators that monitor the value of the counter; when either comparator matches the counter, they output a single-clock-cycle-width High pulse, labelled "cmpA" and "cmpB" in the figures in this chapter. When in Count-Up/Down mode, these comparators match both when counting up and when counting down, and thus are qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 19-3 on page 1194 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 19-4 on page 1194 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode. In these figures, the following definitions apply:

- LOAD is the value in the **PWMnLOAD** register
- COMPA is the value in the **PWMnCMPA** register
- COMPB is the value in the **PWMnCMPB** register
- 0 is the value zero
- load is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to the load value
- zero is the internal signal that has a single-clock-cycle-width High pulse when the counter is zero

- cmpA is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPA
- cmpB is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPB
- dir is the internal signal that indicates the count direction

**Figure 19-3. PWM Count-Down Mode****Figure 19-4. PWM Count-Up/Down Mode**

### 19.3.3 PWM Signal Generator

Each PWM generator takes the load, zero, cmpA, and cmpB pulses (qualified by the dir signal) and generates two internal PWM signals, pwmA and pwmB. In Count-Down mode, there are four events that can affect these signals: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect these signals: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, pwmA, is

generated based only on the match A event, and the second signal, pwmB, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 19-5 on page 1195 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles. This figure shows the pwmA and pwmB signals before they have passed through the dead-band generator.

**Figure 19-5. PWM Generation Example In Count-Up/Down Mode**

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the pwmA signal, and changing the value of comparator B changes the duty cycle of the pwmB signal.

### 19.3.4 Dead-Band Generator

The pwmA and pwmB signals produced by each PWM generator are passed to the dead-band generator. If the dead-band generator is disabled, the PWM signals simply pass through to the pwmA' and pwmB' signals unmodified. If the dead-band generator is enabled, the pwmB signal is lost and two PWM signals are generated based on the pwmA signal. The first output PWM signal, pwmA' is the pwmA signal with the rising edge delayed by a programmable amount. The second output PWM signal, pwmB', is the inversion of the pwmA signal with a programmable delay added between the falling edge of the pwmA signal and the rising edge of the pwmB' signal.

The resulting signals are a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 19-6 on page 1195 shows the effect of the dead-band generator on the pwmA signal and the resulting pwmA' and pwmB' signals that are transmitted to the output control block.

**Figure 19-6. PWM Dead-Band Generator**

### 19.3.5 Interrupt/ADC-Trigger Selector

Each PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position within the pwmA or pwmB signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

### 19.3.6 Synchronization Methods

Each PWM module provides four PWM generators, each providing two PWM outputs that may be used in a wide variety of applications. Generally speaking, the PWM is used in one of two categories of operation:

- **Unsynchronized.** The PWM generator and its two output signals are used alone, independent of other PWM generators.
- **Synchronized.** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base. If multiple PWM generators are configured with the same counter load value, synchronization can be used to guarantee that they also have the same count value (the PWM generators must be configured before they are synchronized). With this feature, more than two M<sub>n</sub>PW<sub>n</sub> signals can be produced with a known relationship between the edges of those signals because the counters always have the same values. Other states in the module provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the SYNC<sub>n</sub> bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary SYNC<sub>n</sub> bits in one access. For example, setting the SYNC<sub>0</sub> and SYNC<sub>1</sub> bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additional synchronization can occur between multiple PWM generators by updating register contents in one of the following three ways:

- **Immediately.** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized.** The write value does not affect the logic until the counter reaches the value zero at the end of the PWM cycle. In this case, the effect of the write is deferred, providing a guaranteed defined behavior and preventing overly short or overly long output PWM pulses.
- **Globally Synchronized.** The write value does not affect the logic until two sequential events have occurred: (1) the Update mode for the generator function is programmed for global synchronization in the **PWM<sub>n</sub>CTL** register, and (2) the counter reaches zero at the end of the PWM cycle. In this case, the effect of the write is deferred until the end of the PWM cycle following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of various Update mode bits and fields in the **PWMnCTL** register (LOADUPD; CMPAUPD; CMPBUPD):

- Generator Registers: **PWMnLOAD**, **PWMnCMPA**, and **PWMnCMPB**

The following registers default to immediate update, but are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect:

- Module-Level Register: **PWMENABLE** (based on the state of the ENUPDn bits in the PWMENUPD register).
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL** (based on the state of various Update mode bits and fields in the **PWMnCTL** register (GENAUPD; GENBUPD; DBCTLUPD; DBRISEUPD; DBFALLUPD)).

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization and therefore do not need synchronous update functionality.

### 19.3.7 Fault Conditions

A fault condition is one in which the controller must be signaled to stop normal PWM function and then set the MnPWMn signals to a safe state. Two basic situations cause fault conditions:

- The microcontroller is stalled and cannot perform the necessary computation in the time required for motion control
- An external error or event is detected

Each PWM generator can use the following inputs to generate a fault condition, including:

- MnFAULTn pin assertion
- A stall of the controller generated by the debugger
- The trigger of an ADC digital comparator

Fault conditions are calculated on a per-PWM generator basis. Each PWM generator configures the necessary conditions to indicate a fault condition exists. This method allows the development of applications with dependent and independent control.

Six fault input pins (MnFAULTn) are available. These inputs may be used with circuits that generate an active High or active Low signal to indicate an error condition. A MnFAULTn pins may be individually programmed for the appropriate logic sense using the **PWMnFLTSEN** register.

The PWM generator's mode control, including fault condition handling, is provided in the **PWMnCTL** register. The **PWMnCTL** register also selects whether the fault condition is maintained as long as the external condition lasts or if it is latched until the fault condition until cleared by software. Finally, this register also enables a counter that may be used to extend the period of a fault condition for external events to assure that the duration is a minimum length. The minimum fault period count is specified in the **PWMnMINFLTPER** register.

Status regarding the specific fault cause is provided in the **PWMnFLTSTAT0** and **PWMnFLTSTAT1** registers.

PWM generator fault conditions may be promoted to a controller interrupt using the **PWMINTEN** register.

### 19.3.8 Output Control Block

The output control block takes care of the final conditioning of the pwmA' and pwmB' signals before they go to the pins as the MnPWMn signals. Via a single register, the **PWM Output Enable (PWENABLE)** register, the set of PWM signals that are actually enabled to the pins can be modified. This function can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). In addition, the updating of the bits in the **PWMENABLE** register can be configured to be immediate or locally or globally synchronized to the next synchronous update using the **PWM Enable Update (PWMENUPE)** register.

During fault conditions, the PWM output signals, MnPWMn, usually must be driven to safe values so that external equipment may be safely controlled. The **PWMFAULT** register specifies whether during a fault condition, the generated signal continues to be passed driven or to an encoding specified in the **PWMFAULTVAL** register.

A final inversion can be applied to any of the MnPWMn signals, making them active Low instead of the default active High using the **PWM Output Inversion (PWMINVERT)**. The inversion is applied even if a value has been enabled in the **PWMFAULT** register and specified in the **PWMFAULTVAL** register. In other words, if a bit is set in the **PWMFAULT**, **PWMFAULTVAL**, and **PWMINVERT** registers, the output on the MnPWMn signal is 0, not 1 as specified in the **PWMFAULTVAL** register.

## 19.4 Initialization and Configuration

The following example shows how to initialize PWM Generator 0 with a 25-kHz frequency, a 25% duty cycle on the MnPWM0 pin, and a 75% duty cycle on the MnPWM1 pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by writing a value of 0x0010.0000 to the **RCGC0** register in the System Control module (see page 463).
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module (see page 471).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 22-4 on page 1307.
4. Configure the PMCN fields in the **GPIOCTL** register to assign the PWM signals to the appropriate pins (see page 661 and Table 22-5 on page 1314).
5. Configure the **Run-Mode Clock Configuration (RCC)** register in the System Control module to use the PWM divide (USEPWMDIV) and set the divider (PWMDIV) to divide by 2 (000).
6. Configure the PWM generator for countdown mode with immediate updates to the parameters.
  - Write the **PWM0CTL** register with a value of 0x0000.0000.
  - Write the **PWM0GENA** register with a value of 0x0000.008C.
  - Write the **PWM0GENB** register with a value of 0x0000.080C.
7. Set the period. For a 25-KHz frequency, the period = 1/25,000, or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. Thus there are 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the LOAD field in the **PWM0LOAD** register to the requested period minus one.

- Write the **PWM0LOAD** register with a value of 0x0000.018F.
- 8. Set the pulse width of the MnPWM0 pin for a 25% duty cycle.
  - Write the **PWM0CMPA** register with a value of 0x0000.012B.
- 9. Set the pulse width of the MnPWM1 pin for a 75% duty cycle.
  - Write the **PWM0CMPB** register with a value of 0x0000.0063.
- 10. Start the timers in PWM generator 0.
  - Write the **PWM0CTL** register with a value of 0x0000.0001.
- 11. Enable PWM outputs.
  - Write the **PWMENABLE** register with a value of 0x0000.0003.

## 19.5 Register Map

Table 19-2 on page 1199 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM module's base address:

- PWM0: 0x4002.8000
- PWM1: 0x4002.9000

Note that the PWM module clock must be enabled before the registers can be programmed (see page 463). There must be a delay of 3 system clocks after the PWM module clock is enabled before any PWM module registers are accessed.

**Table 19-2. PWM Register Map**

| Offset | Name        | Type  | Reset       | Description                       | See page |
|--------|-------------|-------|-------------|-----------------------------------|----------|
| 0x000  | PWMCTL      | R/W   | 0x0000.0000 | PWM Master Control                | 1203     |
| 0x004  | PWMSYNC     | R/W   | 0x0000.0000 | PWM Time Base Sync                | 1205     |

## 19.6 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

**Register 1: PWM Master Control (PWMCTL), offset 0x000**

This register provides master control over the PWM generation blocks.

**PWM Master Control (PWMCTL)**

PWM0 base: 0x4002.8000  
 PWM1 base: 0x4002.9000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

|       |          |    |    |    |    |    |    |    |    |    |    |    |             |             |             |             |

## Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Setting a bit in this register causes the specified counter to reset back to 0; setting multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

**Register 3: PWM Output Enable (PWMENABLE), offset 0x008**

This register provides a master control of which generated pwmA' and pwmB' signals are output to the MnPWMn pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding pwmA' or pwmB' signal is passed through to the output stage. When bits are clear, the pwmA' or pwmB' signal is replaced by a zero value which is also passed to the output stage. The **PWMINVERT** register controls the output stage, so if the corresponding bit is set in that register, the value seen on the MnPWMn signal is inverted from what is configured by the bits in this register. Updates to the bits in this register can be immediate or locally or globally synchronized to the next synchronous update as controlled by the ENUPDn fields in the **PWMENUPD** register.

**PWM Output Enable (PWMENABLE)**

**Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C**

This register provides a master control of the polarity of the MnPWMn signals on the device pins. The pwmA' and pwmB' signals generated by the PWM generator are active High; but can be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive signals can be High. In addition, if the **PWMFAULT** register enables a specific value to be placed on the MnPWMn signals during a fault condition, that value is inverted if the corresponding bit in this register is set.

**PWM Output Inversion (PWMINVERT)**

**Register 5: PWM Output Fault (PWMFAULT), offset 0x010**

This register controls the behavior of the MnPWMn outputs in the presence of fault conditions. Both the fault inputs (MnFAULTn pins and digital comparator outputs) and debug events are considered fault conditions. On a fault condition, each pwmA' or pwmB' signal can be passed through unmodified or driven to the value specified by the corresponding bit in the **PWMFAULTVAL** register. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the pwmA' or pwmB' signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

**Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014**

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generators.

**Note:** The "n" in the INTFAULTn and INTPWMn bits in this register correspond to the PWM generators, not to the FAULTn signals.

**PWM Interrupt Enable (PWMINTEN)**

PWM0 base: 0x4002.8000

PWM1 base: 0x4002.9000

Offset 0x014

Type R/W, reset 0x0000.0000

**Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018**

This register provides the current set of interrupt sources that are asserted, regardless of whether they are enabled to cause an interrupt to be asserted to the interrupt controller. The fault interrupt is asserted based on the fault condition source that is specified by the **PWMnCTL**, **PWMnFLTSRC0** and **PWMnFLTSRC1** registers. The fault interrupt is latched on detection and must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register. The actual value of the MnFAULTn signals can be observed using the **PWMSTATUS** register.

The PWM generator interrupts simply reflect the status of the PWM generators and are cleared via the interrupt status register in the PWM generator blocks. If a bit is set, the event is active; if a bit is clear the event is not active.

**PWM Raw Interrupt Status (PWMRIS)**

PWM0 base: 0x4002.8000

PWM1 base: 0x4002.9000

Offset 0x018

Type RO, reset 0x0000.0000

## Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the individual PWM generator blocks. If a fault interrupt is set, the corresponding MnFAULTn input has caused an interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status. If an block interrupt bit is set, the corresponding generator block is asserting an interrupt. The individual interrupt status registers, **PWMnISC**, in each block must be consulted to determine the reason for the interrupt and used to clear the interrupt.

### PWM Interrupt Status and Clear (PWMISC)

PWM0 base: 0x4002.8000  
 PWM1 base: 0x4002.9000  
 Offset 0x01C  
 Type R/W1C, reset 0x0000.0000

Value Description

1 An enabled interrupt for the PWM generator 0 block is asserted.

0 The PWM generator 0 block interrupt is not asserted or is not enabled.

The **PWM0RIS** register shows the source of this interrupt. This bit is cleared by writing a 1 to the corresponding bit in the **PWM0ISC** register.

**Register 9: PWM Status (PWMSTATUS), offset 0x020**

This register provides the unlatched status of the PWM generator fault condition.

**PWM Status (PWMSTATUS)**

PWM0 base: 0x4002.8000

PWM1 base: 0x4002.9000

Offset 0x020

Type RO, reset 0x0000.0000

**Register 10: PWM Fault Condition Value (PWMFAULTVAL), offset 0x024**

This register specifies the output value driven on the MnPWMn signals during a fault condition if enabled by the corresponding bit in the **PWMFAULT** register. Note that if the corresponding bit in the **PWMINVERT** register is set, the output value is driven to the logical NOT of the bit value in this register.

**PWM Fault Condition Value (PWMFAULTVAL)**

PWM0 base: 0x4002.8000

**Register 11: PWM Enable Update (PWMENUPD), offset 0x028**

This register specifies when updates to the PWMnEN bit in the **PWMENABLE** register are performed. The PWMnEN bit enables the pwmA' or pwmB' output to be passed to the microcontroller's pin. Updates can be immediate or locally or globally synchronized to the next synchronous update.

**PWM Enable Update (PWMENUPD)**

**Register 12: PWM0 Control (PWM0CTL), offset 0x040****Register 13: PWM1 Control (PWM1CTL), offset 0x080****Register 14: PWM2 Control (PWM2CTL), offset 0x0C0****Register 15: PWM3 Control (PWM3CTL), offset 0x100**

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the MnPWM0 and MnPWM1 outputs, the PWM1 block produces the MnPWM2 and MnPWM3 outputs, the PWM2 block produces the MnPWM4 and MnPWM5 outputs, and the PWM3 block produces the MnPWM6 and MnPWM7 outputs.

**PWMn Control (PWMnCTL)**

PWM0 base: 0x4002.8000

PWM1 base: 0x4002.9000

Offset 0x040

Type R/W, reset 0x0000.0000

| 17        | MINFLTPER | R/W  | 0     | <p>Minimum Fault Period</p> <p>This bit specifies that the PWM generator enables a one-shot counter to provide a minimum fault condition period.</p> <p>The timer begins counting on the rising edge of the fault condition to extend the condition for a minimum duration of the count value. The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the MINFLTPER bit is set. If a detected fault is in the process of being extended when the MINFLTPER bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the <b>PWMnMINFLTPER</b> register MFP field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is <math>PWMClock * (MFP \text{ value} + 1)</math> or <math>PWMClock * (MFP \text{ value} + 2)</math>.</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the FLTSRC field.</p> <p>Value Description</p> <p>0 The FAULT input deassertion is unaffected.</p> <p>1 The <b>PWMnMINFLTPER</b> one-shot counter is active and extends the period of the fault condition to a minimum period.</p> |
| 16        | FLTSRC    | R/W  | 0     | <p>Fault Condition Source</p> <p>Value Description</p> <p>0 The Fault condition is determined by the Fault0 input.</p> <p>1 The Fault condition is determined by the configuration of the <b>PWMnFLTSRC0</b> and <b>PWMnFLTSRC1</b> registers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 1         | MODE   | R/W  | 0     | Counter Mode<br><br>Value Description<br>0 The counter counts down from the load value to 0 and then wraps back to the load value (Count-Down mode).<br>1 The counter counts up from 0 to the load value, back down to 0, and then repeats (Count-Up/Down mode). |
| 0         | ENABLE | R/W  | 0     | PWM Block Enable<br><br>Value Description<br>0 The entire PWM generation block is disabled and not clocked.<br>1 The PWM generation block is enabled and produces PWM signals.                                                                                   |

**Register 16: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044**

**Register 17: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084**

**Register 18: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4**

**Register 19: PWM3 Interrupt and Trigger Enable (PWM3INTEN), offset 0x104**

These registers control the interrupt and ADC trigger generation capabilities of the PWM generators (**PWM0INTEN** controls the PWM generator 0 block, and so on). The events that can cause an interrupt, or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the **PWMnCMPA** register while counting up
- The counter being equal to the **PWMnCMPA** register while counting down
- The counter being equal to the **PWMnCMB** register while counting up
- The counter being equal to the **PWMnCMB** register while counting down

Any combination of these events can generate either an interrupt or an ADC trigger, though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified. The **PWMnRIS** register provides information about which events have caused raw interrupts.

#### PWMn Interrupt and Trigger Enable (PWMnINTEN)

PWM0 base: 0x4002.8000  
 PWM1 base: 0x4002.9000  
 Offset 0x044  
 Type R/W, reset 0x0000.0000

**Register 20: PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048****Register 21: PWM1 Raw Interrupt Status (PWM1RIS), offset 0x088****Register 22: PWM2 Raw Interrupt Status (PWM2RIS), offset 0x0C8****Register 23: PWM3 Raw Interrupt Status (PWM3RIS), offset 0x108**

These registers provide the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (**PWM0RIS** controls the PWM generator 0 block, and so on). If a bit is set, the event has occurred; if a bit is clear, the event has not occurred. Bits in this register are cleared by writing a 1 to the corresponding bit in the **PWMnISC** register.

**PWMn Raw Interrupt Status (PWMnRIS)**

**Register 24: PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C****Register 25: PWM1 Interrupt Status and Clear (PWM1ISC), offset 0x08C****Register 26: PWM2 Interrupt Status and Clear (PWM2ISC), offset 0x0CC****Register 27: PWM3 Interrupt Status and Clear (PWM3ISC), offset 0x10C**

These registers provide the current set of interrupt sources that are asserted to the interrupt controller (**PWM0ISC** controls the PWM generator 0 block, and so on). A bit is set if the event has occurred and is enabled in the **PWMnINTEN** register; if a bit is clear, the event has not occurred or is not enabled. These are R/W1C registers; writing a 1 to a bit position clears the corresponding interrupt reason.

**Register 28: PWM0 Load (PWM0LOAD), offset 0x050****Register 29: PWM1 Load (PWM1LOAD), offset 0x090****Register 30: PWM2 Load (PWM2LOAD), offset 0x0D0****Register 31: PWM3 Load (PWM3LOAD), offset 0x110**

These registers contain the load value for the PWM counter (**PWM0LOAD** controls the PWM generator 0 block, and so on). Based on the counter mode configured by the **MODE** bit in the **PWMnCTL** register, this value is either loaded into the counter after it reaches zero or is the limit of up-counting after which the counter decrements back to zero. When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and/or pwmB signal (via the **PWMnGENA/PWMnGENB** register) or drive an interruptor ADC trigger (via the **PWMnINTEN** register).

If the Load Value Update mode is locally synchronized (based on the **LOADUPD** field encoding in the **PWMnCTL** register), the 16-bit **LOAD** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1203). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

**PWMn Load (PWMnLOAD)**

**Register 44: PWM0 Generator A Control (PWM0GENA), offset 0x060****Register 45: PWM1 Generator A Control (PWM1GENA), offset 0x0A0****Register 46: PWM2 Generator A Control (PWM2GENA), offset 0x0E0****Register 47: PWM3 Generator A Control (PWM3GENA), offset 0x120**

These registers control the generation of the pwmA signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENA** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENA** register controls generation of the pwm0A signal; **PWM1GENA**, the pwm1A signal; **PWM2GENA**, the pwm2A signal; and **PWM3GENA**, the pwm3A signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the GENAUPD field encoding in the **PWMnCTL** register), the ACTCMPBD, ACTCMPBU, ACTCMPAD, ACTCMPAU, ACTLOAD, and ACTZERO values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1203). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 48: PWM0 Generator B Control (PWM0GENB), offset 0x064****Register 49: PWM1 Generator B Control (PWM1GENB), offset 0x0A4****Register 50: PWM2 Generator B Control (PWM2GENB), offset 0x0E4****Register 51: PWM3 Generator B Control (PWM3GENB), offset 0x124**

These registers control the generation of the pwmB signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENB** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENB** register controls generation of the pwm0B signal; **PWM1GENB**, the pwm1B signal; **PWM2GENB**, the pwm2B signal; and **PWM3GENB**, the pwm3B signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

If the Generator B update mode is immediate (based on the GENBUPD field encoding in the **PWMnCTL** register), the ACTCMPBD, ACTCMPBU, ACTCMPAD, ACTCMPAU, ACTLOAD, and ACTZERO values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1203). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWMn Generator B Control (PWMnGENB), offset 0x064**

PWM0 base: 0x4002.8000

PWM1 base: 0x4002.9000

Offset 0x064

Type R/W, reset 0x0000.0000

**Register 52: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068****Register 53: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8****Register 54: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8****Register 55: PWM3 Dead-Band Control (PWM3DBCTL), offset 0x128**

The **PWMnDBCTL** register controls the dead-band generator, which produces the MnPWMn signals based on the pwmA and pwmB signals. When disabled, the pwmA signal passes through to the pwmA' signal and the pwmB signal passes through to the pwmB' signal. When dead-band control is enabled, the pwmB signal is ignored, the pwmA' signal is generated by delaying the rising edge(s) of the pwmA signal by the value in the **PWMnDBRISE** register (see page 1251), and the pwmB' signal is generated by inverting the pwmA signal and delaying the falling edge(s) of the pwmA signal by the value in the **PWMnDBFALL** register (see page 1252). The Output Control block outputs the pwm0A' signal on the MnPWM0 signal and the pwm0B' signal on the MnPWM1 signal. In a similar manner, MnPWM2 and MnPWM3 are produced from the pwm1A' and pwm1B' signals, MnPWM4 and MnPWM5 are produced from the pwm2A' and pwm2B' signals, and MnPWM6 and MnPWM7 are produced from the pwm3A' and pwm3B' signals.

If the Dead-Band Control mode is immediate (based on the DBCTLUPD field encoding in the **PWMnCTL** register), the ENABLE bit value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1203). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

| 0                 | The pwmA and pwmB signals pass through to the pwmA' and pwmB' signals unmodified.                          |      |            |                                                                                                                                                                                               |

**Register 56: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C**

**Register 57: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC**

**Register 58: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC**

**Register 59: PWM3 Dead-Band Rising-Edge Delay (PWM3DBRISE), offset 0x12C**

The **PWMnDBRISE** register contains the number of clock cycles to delay the rising edge of the pwmA signal when generating the pwmA' signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a High pulse on the pwmA signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the pwmA High time always exceeds the rising-edge delay.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the DBRISEUPD field encoding in the **PWMnCTL** register), the 12-bit RISEDELAY value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1203). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

|-----------|-----------|------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:12     | reserved  | RO   | 0x0000.0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11:0      | RISEDELAY | R/W  | 0x000    | Dead-Band Rise Delay<br>The number of clock cycles to delay the rising edge of pwmA' after the rising edge of pwmA.                                                                           |

**Register 60: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070**

**Register 61: PWM1 Dead-Band Falling-Edge-Delay (PWM1DBFALL), offset 0x0B0**

**Register 62: PWM2 Dead-Band Falling-Edge-Delay (PWM2DBFALL), offset 0x0F0**

**Register 63: PWM3 Dead-Band Falling-Edge-Delay (PWM3DBFALL), offset 0x130**

The **PWMnDBFALL** register contains the number of clock cycles to delay the rising edge of the pwmB' signal from the falling edge of the pwmA signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a Low pulse on the pwmA signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the pwmA Low time always exceeds the falling-edge delay.

If the Dead-Band Falling-Edge-Delay mode is immediate (based on the DBFALLUP field encoding in the **PWMnCTL** register), the 12-bit FALLDELAY value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1203). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

| 11:0      | FALLDELAY | R/W  | 0x000    | Dead-Band Fall Delay<br>The number of clock cycles to delay the falling edge of pwmB' from the rising edge of pwmA.                                                                           |

**Register 64: PWM0 Fault Source 0 (PWM0FLTSRC0), offset 0x074****Register 65: PWM1 Fault Source 0 (PWM1FLTSRC0), offset 0x0B4****Register 66: PWM2 Fault Source 0 (PWM2FLTSRC0), offset 0x0F4****Register 67: PWM3 Fault Source 0 (PWM3FLTSRC0), offset 0x134**

This register specifies which fault pin inputs are used to generate a fault condition. Each bit in the following register indicates whether the corresponding fault pin is included in the fault condition. All enabled fault pins are ORed together to form the **PWMnFLTSRC0** portion of the fault condition. The **PWMnFLTSRC0** fault condition is then ORed with the **PWMnFLTSRC1** fault condition to generate the final fault condition for the PWM generator.

If the FLTSRC bit in the **PWMnCTL** register (see page 1228) is clear, only the **Fault0** signal affects the fault condition generated. Otherwise, sources defined in **PWMnFLTSRC0** and **PWMnFLTSRC1** affect the fault condition generated.

**PWMn Fault Source 0 (PWMnFLTSRC0)**

**Register 68: PWM0 Fault Source 1 (PWM0FLTSRC1), offset 0x078****Register 69: PWM1 Fault Source 1 (PWM1FLTSRC1), offset 0x0B8****Register 70: PWM2 Fault Source 1 (PWM2FLTSRC1), offset 0x0F8****Register 71: PWM3 Fault Source 1 (PWM3FLTSRC1), offset 0x138**

This register specifies which digital comparator triggers from the ADC are used to generate a fault condition. Each bit in the following register indicates whether the corresponding digital comparator trigger is included in the fault condition. All enabled digital comparator triggers are ORed together to form the **PWMnFLTSRC1** portion of the fault condition. The **PWMnFLTSRC1** fault condition is then ORed with the **PWMnFLTSRC0** fault condition to generate the final fault condition for the PWM generator.

If the FLTSRC bit in the **PWMnCTL** register (see page 1228) is clear, only the PWM Fault pin affects the fault condition generated. Otherwise, sources defined in **PWMnFLTSRC0** and **PWMnFLTSRC1** affect the fault condition generated.

**PWMn Fault Source 1 (PWMnFLTSRC1)**

**Register 72: PWM0 Minimum Fault Period (PWM0MINFLTPER), offset 0x07C**

**Register 73: PWM1 Minimum Fault Period (PWM1MINFLTPER), offset 0x0BC**

**Register 74: PWM2 Minimum Fault Period (PWM2MINFLTPER), offset 0x0FC**

**Register 75: PWM3 Minimum Fault Period (PWM3MINFLTPER), offset 0x13C**

If the MINFLTPER bit in the **PWMnCTL** register is set, this register specifies the 16-bit time-extension value to be used in extending the fault condition. The value is loaded into a 16-bit down counter, and the counter value is used to extend the fault condition. The fault condition is released in the clock immediately after the counter value reaches 0. The fault condition is asynchronous to the PWM clock; and the delay value is the product of the PWM clock period and the (MFP field value + 1) or (MFP field value + 2) depending on when the fault condition asserts with respect to the PWM clock. The counter decrements at the PWM clock rate, without pause or condition.

**Register 80: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804**

**Register 81: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884**

**Register 82: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904**

**Register 83: PWM3 Fault Status 0 (PWM3FLTSTAT0), offset 0x984**

Along with the **PWMnFLTSTAT1** register, this register provides status regarding the fault condition inputs.

If the LATCH bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT0** register are read-only (RO) and provide the current state of the MnFAULTn inputs.

If the LATCH bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT0** register are read / write 1 to clear (R/W1C) and provide a latched version of the MnFAULTn inputs. In this mode, the register bits are cleared by writing a 1 to a set bit. The MnFAULTn inputs are recorded after their sense is adjusted in the generator.

The contents of this register can only be written if the fault source extensions are enabled (the FLTSRC bit in the **PWMnCTL** register is set).

**Register 84: PWM0 Fault Status 1 (PWM0FLTSTAT1), offset 0x808****Register 85: PWM1 Fault Status 1 (PWM1FLTSTAT1), offset 0x888****Register 86: PWM2 Fault Status 1 (PWM2FLTSTAT1), offset 0x908****Register 87: PWM3 Fault Status 1 (PWM3FLTSTAT1), offset 0x988**

Along with the **PWMnFLTSTAT0** register, this register provides status regarding the fault condition inputs.

If the LATCH bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT1** register are read-only (RO) and provide the current state of the digital comparator triggers.

If the LATCH bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT1** register are read / write 1 to clear (R/W1C) and provide a latched version of the digital comparator triggers. In this mode, the register bits are cleared by writing a 1 to a set bit. The contents of this register can only be written if the fault source extensions are enabled (the FLTSRC bit in the **PWMnCTL** register is set).

**PWMn Fault Status 1 (PWMnFLTSTAT1)**

**Register 88: PWM Peripheral Properties (PWMPP), offset 0xFC0**

The **PWMPP** register provides information regarding the properties of the PWM module.

**PWM Peripheral Properties (PWMPP)**

PWM0 base: 0x4002.8000

PWM1 base: 0x4002.9000

Offset 0xFC0

Type RO, reset 0x0000.0334

## 20 Quadrature Encoder Interface (QEI)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The LM4F231H5QR microcontroller includes two quadrature encoder interface (QEI) modules. Each QEI module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The Stellaris<sup>®</sup> LM4F231H5QR microcontroller includes two QEI modules providing control of two motors at the same time with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

### 20.1 Block Diagram

Figure 20-1 on page 1269 provides a block diagram of a Stellaris QEI module.

Figure 20-1. QEI Block Diagram

## 20.2 Signal Description

The following table lists the external signals of the QEI module and describes the function of each. The QEI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these QEI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 644) should be set to choose the QEI function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 661) to assign the QEI signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 623.

Table 20-1. QEI Signals (64LQFP) (continued)

| Pin Name | Pin Number     | Pin Mux / Pin Assignment      | Pin Type | Buffer Type <sup>a</sup> | Description           |
|----------|----------------|-------------------------------|----------|--------------------------|-----------------------|
| PhB1     | 14<br>33<br>36 | PC6 (6)<br>PG4 (6)<br>PG1 (6) | I        | TTL                      | QEI module 1 phase B. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 20.3 Functional Description

The QEI module interprets the two-bit gray code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The position integrator and velocity capture can be independently enabled, though the position integrator must be enabled before the velocity capture can be enabled. The two phase signals, PhA and PhB, can be swapped before being interpreted by the QEI module to change the meaning of forward and backward and to correct for miswiring of the system. Alternatively, the phase signals can be interpreted as a clock and direction signal as output by some encoders.

The QEI module input signals have a digital noise filter on them that can be enabled to prevent spurious operation. The noise filter requires that the inputs be stable for a specified number of consecutive clock cycles before updating the edge detector. The filter is enabled by the FILTEN bit in the **QEI Control (QEICTL)** register. The frequency of the input update is programmable using the FILCNT bit field in the **QEICTL** register.

The QEI module supports two modes of signal operation: quadrature phase mode and clock/direction mode. In quadrature phase mode, the encoder produces two clocks that are 90 degrees out of phase; the edge relationship is used to determine the direction of rotation. In clock/direction mode, the encoder produces a clock signal to indicate steps and a direction signal to indicate the direction of rotation. This mode is determined by the SIGMODE bit of the **QEICTL** register (see page 1274).

When the QEI module is set to use the quadrature phase mode (SIGMODE bit is clear), the capture mode for the position integrator can be set to update the position counter on every edge of the PhA signal or to update on every edge of both PhA and PhB. Updating the position counter on every PhA and PhB edge provides more positional resolution at the cost of less range in the positional counter.

When edges on PhA lead edges on PhB, the position counter is incremented. When edges on PhB lead edges on PhA, the position counter is decremented. When a rising and falling edge pair is seen on one of the phases without any edges on the other, the direction of rotation has changed.

The positional counter is automatically reset on one of two conditions: sensing the index pulse or reaching the maximum position value. The reset mode is determined by the RESMODE bit of the **QEICTL** register.

When RESMODE is set, the positional counter is reset when the index pulse is sensed. This mode limits the positional counter to the values [0:N-1], where N is the number of phase edges in a full revolution of the encoder wheel. The **QEI Maximum Position (QEIMAXPOS)** register must be programmed with N-1 so that the reverse direction from position 0 can move the position counter to N-1. In this mode, the position register contains the absolute position of the encoder relative to the index (or home) position once an index pulse has been seen.

When RESMODE is clear, the positional counter is constrained to the range [0:M], where M is the programmable maximum value. The index pulse is ignored by the positional counter in this mode.

Velocity capture uses a configurable timer and a count register. The timer counts the number of phase edges (using the same configuration as for the position integrator) in a given time period. The edge count from the previous time period is available to the controller via the **QE Velocity (QEISPEED)** register, while the edge count for the current time period is being accumulated in the **QE Velocity Counter (QEICOUNT)** register. As soon as the current time period is complete, the total number of edges counted in that time period is made available in the **QEISPEED** register (overwriting the previous value), the **QEICOUNT** register is cleared, and counting commences on a new time period. The number of edges counted in a given time period is directly proportional to the velocity of the encoder.

Figure 20-2 on page 1271 shows how the Stellaris quadrature encoder converts the phase input signals into clock pulses, the direction signal, and how the velocity predivider operates (in Divide by 4 mode).

**Figure 20-2. Quadrature Encoder and Velocity Predivider Operation**

The period of the timer is configurable by specifying the load value for the timer in the **QE Timer Load (QEILoad)** register. When the timer reaches zero, an interrupt can be triggered, and the hardware reloads the timer with the **QEILoad** value and continues to count down. At lower encoder speeds, a longer timer period is required to be able to capture enough edges to have a meaningful result. At higher encoder speeds, both a shorter timer period and/or the velocity predivider can be used.

The following equation converts the velocity counter value into an rpm value:

$$\text{rpm} = (\text{clock} * (2 ^ \text{VELDIV}) * \text{SPEED} * 60) \div (\text{LOAD} * \text{ppr} * \text{edges})$$

where:

clock is the controller clock rate

ppr is the number of pulses per revolution of the physical encoder

edges is 2 or 4, based on the capture mode set in the **QEICTL** register (2 for CAPMODE clear and 4 for CAPMODE set)

For example, consider a motor running at 600 rpm. A 2048 pulse per revolution quadrature encoder is attached to the motor, producing 8192 phase edges per revolution. With a velocity predivider of ÷1 (VELDIV is clear) and clocking on both PhA and PhB edges, this results in 81,920 pulses per second (the motor turns 10 times per second). If the timer were clocked at 10,000 Hz, and the load value was 2,500 (¼ of a second), it would count 20,480 pulses per update. Using the above equation:

$$\text{rpm} = (10000 * 1 * 20480 * 60) \div (2500 * 2048 * 4) = 600 \text{ rpm}$$

Now, consider that the motor is sped up to 3000 rpm. This results in 409,600 pulses per second, or 102,400 every ¼ of a second. Again, the above equation gives:

$$\text{rpm} = (10000 * 1 * 102400 * 60) \div (2500 * 2048 * 4) = 3000 \text{ rpm}$$

Care must be taken when evaluating this equation because intermediate values may exceed the capacity of a 32-bit integer. In the above examples, the clock is 10,000 and the divider is 2,500; both could be predivided by 100 (at compile time if they are constants) and therefore be 100 and 25. In fact, if they were compile-time constants, they could also be reduced to a simple multiply by 4, cancelled by the  $\div 4$  for the edge-count factor.

---

**Important:** Reducing constant factors at compile time is the best way to control the intermediate values of this equation and reduce the processing requirement of computing this equation.

---

The division can be avoided by selecting a timer load value such that the divisor is a power of 2; a simple shift can therefore be done in place of the division. For encoders with a power of 2 pulses per revolution, the load value can be a power of 2. For other encoders, a load value must be selected such that the product is very close to a power of 2. For example, a 100 pulse-per-revolution encoder could use a load value of 82, resulting in 32,800 as the divisor, which is 0.09% above  $2^{14}$ . In this case a shift by 15 would be an adequate approximation of the divide in most cases. If absolute accuracy were required, the microcontroller's divide instruction could be used.

The QEI module can produce a controller interrupt on several events: phase error, direction change, reception of the index pulse, and expiration of the velocity timer. Standard masking, raw interrupt status, interrupt status, and interrupt clear capabilities are provided.

## 20.4 Initialization and Configuration

The following example shows how to configure the Quadrature Encoder module to read back an absolute position:

1. Enable the QEI clock using the **RCGCQEI** register in the System Control module (see page 333).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 319).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 22-4 on page 1307.
4. Configure the PMCN fields in the **GPIOPCTL** register to assign the QEI signals to the appropriate pins (see page 661 and Table 22-5 on page 1314).
5. Configure the quadrature encoder to capture edges on both signals and maintain an absolute position by resetting on index pulses. A 1000-line encoder with four edges per line, results in 4000 pulses per revolution; therefore, set the maximum position to 3999 (0xF9F) as the count is zero-based.
  - Write the **QEICTL** register with the value of 0x0000.0018.
  - Write the **QEIMAXPOS** register with the value of 0x0000.0F9F.
6. Enable the quadrature encoder by setting bit 0 of the **QEICTL** register.
7. Delay until the encoder position is required.
8. Read the encoder position by reading the **QEI Position (QEIPOS)** register value.

## 20.5 Register Map

Table 20-2 on page 1273 lists the QEI registers. The offset listed is a hexadecimal increment to the register's address, relative to the module's base address:

- QEIO: 0x4002.C000
- QEI1: 0x4002.D000

Note that the QEI module clock must be enabled before the registers can be programmed (see page 333). There must be a delay of 3 system clocks after the QEI module clock is enabled before any QEI module registers are accessed.

**Table 20-2. QEI Register Map**

| Offset | Name      | Type  | Reset       | Description                    | See page |
|--------|-----------|-------|-------------|--------------------------------|----------|
| 0x000  | QEICTL    | R/W   | 0x0000.0000 | QEI Control                    | 1274     |

## 20.6 Register Descriptions

The remainder of this section lists and describes the QEI registers, in numerical order by address offset.

## Register 1: QEI Control (QEICTL), offset 0x000

This register contains the configuration of the QEI module. Separate enables are provided for the quadrature encoder and the velocity capture blocks; the quadrature encoder must be enabled in order to capture the velocity, but the velocity does not need to be captured in applications that do not need it. The phase signal interpretation, phase swap, Position Update mode, Position Reset mode, and velocity predivider are all set via this register.

### QEI Control (QEICTL)

| 31:0      | POSITION | R/W  | 0x0000.0000 | Current Position Integrator Value<br>The current value of the position integrator. |

**Register 4: QEI Maximum Position (QEIMAXPOS), offset 0x00C**

This register contains the maximum value of the position integrator. When moving forward, the position register resets to zero when it increments past this value. When moving in reverse, the position register resets to this value when it decrements from zero.

**QEI Maximum Position (QEIMAXPOS)**

QEI0 base: 0x4002.C000

Register 5: QEI Timer Load (QEILOAD), offset 0x010

This register contains the load value for the velocity timer. Because this value is loaded into the timer on the clock cycle after the timer is zero, this value should be one less than the number of clocks in the desired period. So, for example, to have 2000 decimal clocks per timer period, this register should contain 1999 decimal.

Register 7: QEI Velocity Counter (QEICOUNT), offset 0x018

This register contains the running count of velocity pulses for the current time period. Because this count is a running total, the time period to which it applies cannot be known with precision (that is, a read of this register does not necessarily correspond to the time returned by the **QEITIME** register because there is a small window of time between the two reads, during which either value may have changed). The **QEISPEED** register should be used to determine the actual encoder velocity; this register is provided for information purposes only. This counter does not increment when the VELEN bit in the **QEICTL** register is clear.

QEI Velocity Counter (QEICOUNT)

## Register 10: QEI Raw Interrupt Status (QEIRIS), offset 0x024

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (configured through the **QEINTEN** register). If a bit is set, the latched event has occurred; if a bit is clear, the event in question has not occurred.

### QEI Raw Interrupt Status (QEIRIS)

## Register 11: QEI Interrupt Status and Clear (QEISC), offset 0x028

This register provides the current set of interrupt sources that are asserted to the controller. If a bit is set, the latched event has occurred and is enabled to generate an interrupt; if a bit is clear the event in question has not occurred or is not enabled to generate an interrupt. This register is R/W1C; writing a 1 to a bit position clears the bit and the corresponding interrupt reason.

## 21 Pin Diagram

The LM4F231H5QR microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 22-5 on page 1314.

**Figure 21-1. 64-Pin LQFP Package Pin Diagram**

## 22 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 660) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 644) must be set. Further pin muxing options are provided through the PMCx bit field in the **GPIOPCTL** register (see page 661), which selects one of several available peripheral functions for that GPIO.

**Important:** All GPIO pins are configured as GPIOs by default with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 22-1. GPIO Pins With Default Alternate Functions**

| GPIO Pin | Default State     | GPIOAFSEL Bit | GPIOPCTL PMCx Bit Field |
|----------|-------------------|---------------|-------------------------|
| PA[1:0]  | UART0             | 0             | 0x1                     |
| PA[5:2]  | SSI0              | 0             | 0x1                     |
| PB[3:2]  | I <sup>2</sup> C0 | 0             | 0x1                     |
| PC[3:0]  | JTAG/SWD          | 1             | 0x3                     |

Table 22-2 on page 1292 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 22-3 on page 1300 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the PMCx bit field in the **GPIOPCTL** register.

Table 22-4 on page 1307 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 22-5 on page 1314 lists the GPIO pins and their analog and digital alternate functions. The AINx analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 5-V tolerant and are connected directly to their circuitry (C0-, C0+, C1-, C1+, USB0VBUS, USB0ID). These signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the PMCx bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 22-6 on page 1316 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Stellaris® Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

**Note:** All digital inputs are Schmitt triggered.

Table 22-2. Signals by Pin Number

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                              |

|            | T0CCP0   | I/O      | TTL                      | 16/32-Bit Timer 0 Capture/Compare/PWM 0.                                                                                                                                                                                                                                                         |
|            | U1RTS    | O        | TTL                      | UART module 1 Request to Send modem flow control output line.                                                                                                                                                                                                                                    |

Table 22-2. Signals by Pin Number (*continued*)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                               |
|------------|----------|----------|--------------------------|-----------------------------------------------------------------------------------------------------------|
| 29         | PF1      | I/O      | TTL                      | GPIO port F bit 1.                                                                                        |
|            | C10      | O        | TTL                      | Analog comparator 1 output.                                                                               |
|            | M1PWM5   | O        | TTL                      | Motion Control Module 1 PWM 5. This signal is controlled by Module 1 PWM Generator 2.                     |
|            | PhB0     | I        | TTL                      | QEI module 0 phase B.                                                                                     |
|            | SSI1Tx   | O        | TTL                      | SSI module 1 transmit                                                                                     |
|            | T0CCP1   | I/O      | TTL                      | 16/32-Bit Timer 0 Capture/Compare/PWM 1.                                                                  |
|            | TRD1     | O        | TTL                      | Trace data 1.                                                                                             |
| 30         | U1CTS    | I        | TTL                      | UART module 1 Clear To Send modem flow control input signal.                                              |
|            | PF2      | I/O      | TTL                      | GPIO port F bit 2.                                                                                        |
|            | M0FAULT0 | I        | TTL                      | Motion Control Module 0 PWM Fault 0.                                                                      |
|            | M1PWM6   | O        | TTL                      | Motion Control Module 1 PWM 6. This signal is controlled by Module 1 PWM Generator 3.                     |
|            | SSI1Clk  | I/O      | TTL                      | SSI module 1 clock                                                                                        |
|            | T1CCP0   | I/O      | TTL                      | 16/32-Bit Timer 1 Capture/Compare/PWM 0.                                                                  |
| 31         | TRD0     | O        | TTL                      | Trace data 0.                                                                                             |
|            | PF3      | I/O      | TTL                      | GPIO port F bit 3.                                                                                        |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                                    |
|            | M0FAULT1 | I        | TTL                      | Motion Control Module 0 PWM Fault 1.                                                                      |
|            | M1PWM7   | O        | TTL                      | Motion Control Module 1 PWM 7. This signal is controlled by Module 1 PWM Generator 3.                     |
|            | SSI1Fss  | I/O      | TTL                      | SSI module 1 frame signal                                                                                 |
|            | T1CCP1   | I/O      | TTL                      | 16/32-Bit Timer 1 Capture/Compare/PWM 1.                                                                  |
| 32         | TRCLK    | O        | TTL                      | Trace clock.                                                                                              |
|            | PG5      | I/O      | TTL                      | GPIO port G bit 5.                                                                                        |
|            | I2C1SDA  | I/O      | OD                       | I <sup>2</sup> C module 1 data.                                                                           |
|            | IDX1     | I        | TTL                      | QEI module 1 index.                                                                                       |
|            | M0PWM5   | O        | TTL                      | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.                     |
|            | M1PWM3   | O        | TTL                      | Motion Control Module 1 PWM 3. This signal is controlled by Module 1 PWM Generator 1.                     |
|            | U2Tx     | O        | TTL                      | UART module 2 transmit.                                                                                   |
|            | USB0PFLT | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source. |
| 32         | WT0CCP1  | I/O      | TTL                      | 32/64-Bit Wide Timer 0 Capture/Compare/PWM 1.                                                             |

Table 22-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                      |
|------------|----------|----------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 33         | PG4      | I/O      | TTL                      | GPIO port G bit 4.                                                                                                                               |
|            | I2C1SCL  | I/O      | OD                       | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM4   | O        | TTL                      | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.                                                            |
|            | M1PWM2   | O        | TTL                      | Motion Control Module 1 PWM 2. This signal is controlled by Module 1 PWM Generator 1.                                                            |
|            | PhB1     | I        | TTL                      | QEI module 1 phase B.                                                                                                                            |
|            | U2Rx     | I        | TTL                      | UART module 2 receive.                                                                                                                           |
|            | USB0EPEN | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                 |
| 34         | WT0CCP0  | I/O      | TTL                      | 32/64-Bit Wide Timer 0 Capture/Compare/PWM 0.                                                                                                    |
|            | PG3      | I/O      | TTL                      | GPIO port G bit 3.                                                                                                                               |
|            | I2C4SDA  | I/O      | OD                       | I <sup>2</sup> C module 4 data.                                                                                                                  |
|            | M0FAULT2 | I        | TTL                      | Motion Control Module 0 PWM Fault 2.                                                                                                             |
|            | M1PWM1   | O        | TTL                      | Motion Control Module 1 PWM 1. This signal is controlled by Module 1 PWM Generator 0.                                                            |
|            | PhA1     | I        | TTL                      | QEI module 1 phase A.                                                                                                                            |
| 35         | T5CCP1   | I/O      | TTL                      | 16/32-Bit Timer 5 Capture/Compare/PWM 1.                                                                                                         |
|            | PG2      | I/O      | TTL                      | GPIO port G bit 2.                                                                                                                               |
|            | I2C4SCL  | I/O      | OD                       | I <sup>2</sup> C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0FAULT1 | I        | TTL                      | Motion Control Module 0 PWM Fault 1.                                                                                                             |
|            | M1PWM0   | O        | TTL                      | Motion Control Module 1 PWM 0. This signal is controlled by Module 1 PWM Generator 0.                                                            |
| 36         | T5CCP0   | I/O      | TTL                      | 16/32-Bit Timer 5 Capture/Compare/PWM 0.                                                                                                         |
|            | PG1      | I/O      | TTL                      | GPIO port G bit 1.                                                                                                                               |
|            | I2C3SDA  | I/O      | OD                       | I <sup>2</sup> C module 3 data.                                                                                                                  |
|            | M1FAULT2 | I        | TTL                      | Motion Control Module 1 PWM Fault 2.                                                                                                             |
|            | PhB1     | I        | TTL                      | QEI module 1 phase B.                                                                                                                            |
| 37         | T4CCP1   | I/O      | TTL                      | 16/32-Bit Timer 4 Capture/Compare/PWM 1.                                                                                                         |
|            | PG0      | I/O      | TTL                      | GPIO port G bit 0.                                                                                                                               |
|            | I2C3SCL  | I/O      | OD                       | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M1FAULT1 | I        | TTL                      | Motion Control Module 1 PWM Fault 1.                                                                                                             |
|            | PhA1     | I        | TTL                      | QEI module 1 phase A.                                                                                                                            |
| 38         | T4CCP0   | I/O      | TTL                      | 16/32-Bit Timer 4 Capture/Compare/PWM 0.                                                                                                         |
|            | RST      | I        | TTL                      | System reset input.                                                                                                                              |
| 39         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                         |
| 40         | OSC0     | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                                                                              |
| 41         | OSC1     | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                        |
| 42         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                          |

Table 22-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                   |
|------------|----------|----------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 43         | PD4      | I/O      | TTL                      | GPIO port D bit 4.                                                                                                                                                                                                                                            |
|            | U6Rx     | I        | TTL                      | UART module 6 receive.                                                                                                                                                                                                                                        |
|            | USB0DM   | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                      |
|            | WT4CCP0  | I/O      | TTL                      | 32/64-Bit Wide Timer 4 Capture/Compare/PWM 0.                                                                                                                                                                                                                 |
| 44         | PD5      | I/O      | TTL                      | GPIO port D bit 5.                                                                                                                                                                                                                                            |
|            | U6Tx     | O        | TTL                      | UART module 6 transmit.                                                                                                                                                                                                                                       |
|            | USB0DP   | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                      |
|            | WT4CCP1  | I/O      | TTL                      | 32/64-Bit Wide Timer 4 Capture/Compare/PWM 1.                                                                                                                                                                                                                 |
| 45         | PB0      | I/O      | TTL                      | GPIO port B bit 0. This pin is not 5-V tolerant.                                                                                                                                                                                                              |
|            | T2CCP0   | I/O      | TTL                      | 16/32-Bit Timer 2 Capture/Compare/PWM 0.                                                                                                                                                                                                                      |
|            | U1Rx     | I        | TTL                      | UART module 1 receive.                                                                                                                                                                                                                                        |
|            | USB0ID   | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| 46         | PB1      | I/O      | TTL                      | GPIO port B bit 1. This pin is not 5-V tolerant.                                                                                                                                                                                                              |
|            | T2CCP1   | I/O      | TTL                      | 16/32-Bit Timer 2 Capture/Compare/PWM 1.                                                                                                                                                                                                                      |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit.                                                                                                                                                                                                                                       |
|            | USB0VBUS | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                            |
| 47         | PB2      | I/O      | TTL                      | GPIO port B bit 2.                                                                                                                                                                                                                                            |
|            | I2C0SCL  | I/O      | OD                       | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                                                                              |

Table 22-3. Signals by Signal Name (continued)

| Pin Name | Pin Number     | Pin Mux / Pin Assignment      | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                       |
|----------|----------------|-------------------------------|----------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GNDA     | 3              | fixed                         | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions. |
| I2C0SCL  | 47             | PB2 (3)                       | I/O      | OD                       | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                  |
| I2C0SDA  | 48             | PB3 (3)                       | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                                                                                                                                   |
| I2C1SCL  | 23<br>33       | PA6 (3)<br>PG4 (3)            | I/O      | OD                       | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                  |
| I2C1SDA  | 24<br>32       | PA7 (3)<br>PG5 (3)            | I/O      | OD                       | I <sup>2</sup> C module 1 data.                                                                                                                                                                   |
| I2C2SCL  | 59             | PE4 (3)                       | I/O      | OD                       | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                  |
| I2C2SDA  | 60             | PE5 (3)                       | I/O      | OD                       | I <sup>2</sup> C module 2 data.                                                                                                                                                                   |
| I2C3SCL  | 37<br>61       | PG0 (3)<br>PD0 (3)            | I/O      | OD                       | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                  |
| I2C3SDA  | 36<br>62       | PG1 (3)<br>PD1 (3)            | I/O      | OD                       | I <sup>2</sup> C module 3 data.                                                                                                                                                                   |
| I2C4SCL  | 35             | PG2 (3)                       | I/O      | OD                       | I <sup>2</sup> C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                  |
| I2C4SDA  | 34             | PG3 (3)                       | I/O      | OD                       | I <sup>2</sup> C module 4 data.                                                                                                                                                                   |
| I2C5SCL  | 1              | PB6 (3)                       | I/O      | OD                       | I <sup>2</sup> C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                                  |
| I2C5SDA  | 4              | PB7 (3)                       | I/O      | OD                       | I <sup>2</sup> C module 5 data.                                                                                                                                                                   |
| IDX0     | 5<br>64        | PF4 (6)<br>PD3 (6)            | I        | TTL                      | QEI module 0 index.                                                                                                                                                                               |
| IDX1     | 16<br>32       | PC4 (6)<br>PG5 (6)            | I        | TTL                      | QEI module 1 index.                                                                                                                                                                               |
| M0FAULT0 | 30<br>53<br>63 | PF2 (4)<br>PD6 (4)<br>PD2 (4) | I        | TTL                      | Motion Control Module 0 PWM Fault 0.                                                                                                                                                              |
| M0FAULT1 | 10<br>31<br>35 | PD7 (4)<br>PF3 (4)<br>PG2 (4) | I        | TTL                      | Motion Control Module 0 PWM Fault 1.                                                                                                                                                              |
| M0FAULT2 | 5<br>34        | PF4 (4)<br>PG3 (4)            | I        | TTL                      | Motion Control Module 0 PWM Fault 2.                                                                                                                                                              |
| M0PWM0   | 1              | PB6 (4)                       | O        | TTL                      | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.                                                                                                             |
| M0PWM1   | 4              | PB7 (4)                       | O        | TTL                      | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.                                                                                                             |
| M0PWM2   | 58             | PB4 (4)                       | O        | TTL                      | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.                                                                                                             |

Table 22-3. Signals by Signal Name (continued)

| Pin Name | Pin Number     | Pin Mux / Pin Assignment      | Pin Type | Buffer Type <sup>a</sup> | Description                                                                               |
|----------|----------------|-------------------------------|----------|--------------------------|-------------------------------------------------------------------------------------------|
| M0PWM3   | 57             | PB5 (4)                       | O        | TTL                      | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.     |
| M0PWM4   | 33<br>59       | PG4 (4)<br>PE4 (4)            | O        | TTL                      | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.     |
| M0PWM5   | 32<br>60       | PG5 (4)<br>PE5 (4)            | O        | TTL                      | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.     |
| M0PWM6   | 16<br>61       | PC4 (4)<br>PD0 (4)            | O        | TTL                      | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.     |
| M0PWM7   | 15<br>62       | PC5 (4)<br>PD1 (4)            | O        | TTL                      | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.     |
| M1FAULT0 | 5              | PF4 (5)                       | I        | TTL                      | Motion Control Module 1 PWM Fault 0.                                                      |
| M1FAULT1 | 37             | PG0 (5)                       | I        | TTL                      | Motion Control Module 1 PWM Fault 1.                                                      |
| M1FAULT2 | 36             | PG1 (5)                       | I        | TTL                      | Motion Control Module 1 PWM Fault 2.                                                      |
| M1PWM0   | 35<br>61       | PG2 (5)<br>PD0 (5)            | O        | TTL                      | Motion Control Module 1 PWM 0. This signal is controlled by Module 1 PWM Generator 0.     |
| M1PWM1   | 34<br>62       | PG3 (5)<br>PD1 (5)            | O        | TTL                      | Motion Control Module 1 PWM 1. This signal is controlled by Module 1 PWM Generator 0.     |
| M1PWM2   | 23<br>33<br>59 | PA6 (5)<br>PG4 (5)<br>PE4 (5) | O        | TTL                      | Motion Control Module 1 PWM 2. This signal is controlled by Module 1 PWM Generator 1.     |
| M1PWM3   | 24<br>32<br>60 | PA7 (5)<br>PG5 (5)<br>PE5 (5) | O        | TTL                      | Motion Control Module 1 PWM 3. This signal is controlled by Module 1 PWM Generator 1.     |
| M1PWM4   | 28             | PF0 (5)                       | O        | TTL                      | Motion Control Module 1 PWM 4. This signal is controlled by Module 1 PWM Generator 2.     |
| M1PWM5   | 29             | PF1 (5)                       | O        | TTL                      | Motion Control Module 1 PWM 5. This signal is controlled by Module 1 PWM Generator 2.     |
| M1PWM6   | 30             | PF2 (5)                       | O        | TTL                      | Motion Control Module 1 PWM 6. This signal is controlled by Module 1 PWM Generator 3.     |
| M1PWM7   | 31             | PF3 (5)                       | O        | TTL                      | Motion Control Module 1 PWM 7. This signal is controlled by Module 1 PWM Generator 3.     |
| NMI      | 10<br>28       | PD7 (8)<br>PF0 (8)            | I        | TTL                      | Non-maskable interrupt.                                                                   |
| OSC0     | 40             | fixed                         | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                       |
| OSC1     | 41             | fixed                         | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| PA0      | 17             | -                             | I/O      | TTL                      | GPIO port A bit 0.                                                                        |
| PA1      | 18             | -                             | I/O      | TTL                      | GPIO port A bit 1.                                                                        |

| USB0EPEN | 5<br>14<br>33<br>63  | PF4 (8)<br>PC6 (8)<br>PG4 (8)<br>PD2 (8) | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                                                                                                         |
| USB0ID   | 45                   | PB0                                      | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).                                                                            |
| USB0PFLT | 13<br>32<br>64       | PC7 (8)<br>PG5 (8)<br>PD3 (8)            | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                                                                                                |
| USB0VBUS | 46                   | PB1                                      | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                                                                                                       |
| VDD      | 11<br>26<br>42<br>54 | fixed                                    | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                  |
| VDDA     | 2                    | fixed                                    | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 24-2 on page 1323, regardless of system implementation. |
| VDDC     | 25<br>56             | fixed                                    | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 24-8 on page 1328.                                          |

Table 22-4. Signals by Function, Except for GPIO (*continued*)

| Function | Pin Name | Pin Number     | Pin Type | Buffer Type <sup>a</sup> | Description                                                                           |
|----------|----------|----------------|----------|--------------------------|---------------------------------------------------------------------------------------|
| PWM      | M0FAULT0 | 30<br>53<br>63 | I        | TTL                      | Motion Control Module 0 PWM Fault 0.                                                  |
|          | M0FAULT1 | 10<br>31<br>35 | I        | TTL                      | Motion Control Module 0 PWM Fault 1.                                                  |
|          | M0FAULT2 | 5<br>34        | I        | TTL                      | Motion Control Module 0 PWM Fault 2.                                                  |
|          | M0PWM0   | 1              | O        | TTL                      | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0. |
|          | M0PWM1   | 4              | O        | TTL                      | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0. |
|          | M0PWM2   | 58             | O        | TTL                      | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1. |
|          | M0PWM3   | 57             | O        | TTL                      | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1. |
|          | M0PWM4   | 33<br>59       | O        | TTL                      | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2. |
|          | M0PWM5   | 32<br>60       | O        | TTL                      | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2. |
|          | M0PWM6   | 16<br>61       | O        | TTL                      | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3. |
|          | M0PWM7   | 15<br>62       | O        | TTL                      | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3. |
|          | M1FAULT0 | 5              | I        | TTL                      | Motion Control Module 1 PWM Fault 0.                                                  |
|          | M1FAULT1 | 37             | I        | TTL                      | Motion Control Module 1 PWM Fault 1.                                                  |
|          | M1FAULT2 | 36             | I        | TTL                      | Motion Control Module 1 PWM Fault 2.                                                  |
|          | M1PWM0   | 35<br>61       | O        | TTL                      | Motion Control Module 1 PWM 0. This signal is controlled by Module 1 PWM Generator 0. |
|          | M1PWM1   | 34<br>62       | O        | TTL                      | Motion Control Module 1 PWM 1. This signal is controlled by Module 1 PWM Generator 0. |
|          | M1PWM2   | 23<br>33<br>59 | O        | TTL                      | Motion Control Module 1 PWM 2. This signal is controlled by Module 1 PWM Generator 1. |
|          | M1PWM3   | 24<br>32<br>60 | O        | TTL                      | Motion Control Module 1 PWM 3. This signal is controlled by Module 1 PWM Generator 1. |
|          | M1PWM4   | 28             | O        | TTL                      | Motion Control Module 1 PWM 4. This signal is controlled by Module 1 PWM Generator 2. |
|          | M1PWM5   | 29             | O        | TTL                      | Motion Control Module 1 PWM 5. This signal is controlled by Module 1 PWM Generator 2. |
|          | M1PWM6   | 30             | O        | TTL                      | Motion Control Module 1 PWM 6. This signal is controlled by Module 1 PWM Generator 3. |
|          | M1PWM7   | 31             | O        | TTL                      | Motion Control Module 1 PWM 7. This signal is controlled by Module 1 PWM Generator 3. |

Table 22-4. Signals by Function, Except for GPIO (*continued*)

| Function | Pin Name | Pin Number           | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                              |
|----------|----------|----------------------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power    | GND      | 12<br>27<br>39<br>55 | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                                                 |
|          | GND A    | 3                    | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                                                                        |
|          | VDD      | 11<br>26<br>42<br>54 | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                  |
|          | VDDA     | 2                    | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 24-2 on page 1323, regardless of system implementation. |
|          | VDDC     | 25<br>56             | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 24-8 on page 1328.                                          |
| QEI      | IDX0     | 5<br>64              | I        | TTL                      | QEI module 0 index.                                                                                                                                                                                                                                                                                                                      |
|          | IDX1     | 16<br>32             | I        | TTL                      | QEI module 1 index.                                                                                                                                                                                                                                                                                                                      |
|          | PhA0     | 28<br>53             | I        | TTL                      | QEI module 0 phase A.                                                                                                                                                                                                                                                                                                                    |
|          | PhA1     | 15<br>34<br>37       | I        | TTL                      | QEI module 1 phase A.                                                                                                                                                                                                                                                                                                                    |
|          | PhB0     | 10<br>29             | I        | TTL                      | QEI module 0 phase B.                                                                                                                                                                                                                                                                                                                    |
|          | PhB1     | 14<br>33<br>36       | I        | TTL                      | QEI module 1 phase B.                                                                                                                                                                                                                                                                                                                    |

Table 22-4. Signals by Function, Except for GPIO (*continued*)

| Function                | Pin Name | Pin Number | Pin Type | Buffer Type <sup>a</sup> | Description                                                                               |
|-------------------------|----------|------------|----------|--------------------------|-------------------------------------------------------------------------------------------|
| SSI                     | SSI0Clk  | 19         | I/O      | TTL                      | SSI module 0 clock                                                                        |
|                         | SSI0Fss  | 20         | I/O      | TTL                      | SSI module 0 frame signal                                                                 |

| USB      | USB0DM   | 43                  | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                      |
|          | USB0DP   | 44                  | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                      |
|          | USB0EPEN | 5<br>14<br>33<br>63 | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                              |
|          | USB0ID   | 45                  | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
|          | USB0PFLT | 13<br>32<br>64      | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                     |
|          | USB0VBUS | 46                  | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                            |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 22.1 Connections for Unused Signals

Table 22-7 on page 1320 shows how to handle signals for functions that are not used in a particular system implementation for devices that are in a 64-pin LQFP package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

Table 22-7. Connections for Unused Signals (64-Pin LQFP)

| Function       | Signal Name      | Pin Number | Acceptable Practice                        | Preferred Practice                                             |
|----------------|------------------|------------|--------------------------------------------|----------------------------------------------------------------|
| GPIO           | All unused GPIOs | -          | NC                                         | GND                                                            |
| No Connects    | NC               | -          | NC                                         | NC                                                             |

|                | USB0DP           | 44         | NC                                         | GND                                                            |

## 23 Operating Characteristics

**Table 23-1. Temperature Characteristics**

| Characteristic                         | Symbol | Value       | Unit |
|----------------------------------------|--------|-------------|------|
| Industrial operating temperature range | $T_A$  | -40 to +85  | °C   |
| Unpowered storage temperature range    | $T_S$  | -65 to +150 | °C   |

**Table 23-2. Thermal Characteristics**

| Characteristic                                        | Symbol        | Value                         | Unit |
|-------------------------------------------------------|---------------|-------------------------------|------|
| Thermal resistance (junction to ambient) <sup>a</sup> | $\Theta_{JA}$ | 50 <sup>b</sup>               | °C/W |
| Junction temperature, -40 to +125 <sup>c</sup>        | $T_J$         | $T_A + (P \cdot \Theta_{JA})$ | °C   |

a. Junction to ambient thermal resistance  $\Theta_{JA}$  numbers are determined by a package simulator.

b. Preliminary.

c. Power dissipation is a function of temperature.

**Table 23-3. ESD Absolute Maximum Ratings<sup>a</sup>**

| Parameter Name | Min | Nom | Max | Unit |
|----------------|-----|-----|-----|------|
| $V_{ESDHBM}$   | -   | -   | 2.0 | kV   |
| $V_{ESDCDM}$   | -   | -   | 500 | V    |

a. All Stellaris® parts are ESD tested following the JEDEC standard.

## 24 Electrical Characteristics

### 24.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device. Device reliability may be adversely affected by exposure to absolute-maximum ratings for extended periods.

**Note:** The device is not guaranteed to operate properly at the maximum ratings.

**Table 24-1. Maximum Ratings**

| Parameter             | Parameter Name <sup>a</sup>                                                                                            | Value |                       | Unit |
|-----------------------|------------------------------------------------------------------------------------------------------------------------|-------|-----------------------|------|
|                       |                                                                                                                        | Min   | Max                   |      |
| V <sub>DD</sub>       | V <sub>DD</sub> supply voltage                                                                                         | 0     | 4                     | V    |
| V <sub>DDA</sub>      | V <sub>DDA</sub> supply voltage                                                                                        | 0     | 4                     | V    |
| V <sub>IN_GPIO</sub>  | Input voltage on GPIOs, regardless of whether the microcontroller is powered <sup>bc</sup>                             | -0.3  | 5.5                   | V    |
|                       | Input voltage for PB0 and PB1 when configured as GPIO                                                                  | -0.3  | V <sub>DD</sub> + 0.3 | V    |
| I <sub>GPIO MAX</sub> | Maximum current per output pin                                                                                         | -     | 25                    | mA   |
| I <sub>NON</sub>      | Maximum current into or out of a non-power, non-GPIO, non-XOSCn pin when the microcontroller is unpowered <sup>d</sup> | -     | pending <sup>e</sup>  | mA   |

a. Voltages are measured with respect to GND.

b. Applies to static and dynamic signals including overshoot.

c. Refer to Figure 24-1 on page 1323 for a representation of the ESD protection on GPIOs.

d. Refer to Figure 24-2 on page 1323 for a representation of the ESD protection on these pins.

e. Pending characterization.

**Important:** This device contains circuitry to protect the inputs against damage due to high-static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see “Connections for Unused Signals” on page 1320).

Figure 24-1 on page 1323 shows a diagram of the ESD protection on GPIOs.

**Figure 24-1. ESD Protection on GPIOs**

Figure 24-2 on page 1323 shows a diagram of the ESD protection on non-power, non-GPIO, and non-XOSCn pins.

**Figure 24-2. ESD Protection on Non-Power, Non-GPIO, and Non-XOSCn Pins**

## 24.2 Recommended Operating Conditions

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the  $V_{OL}$  value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

**Table 24-2. Recommended DC Operating Conditions**

| Parameter | Parameter Name                | Min             | Nom | Max             | Unit |
|-----------|-------------------------------|-----------------|-----|-----------------|------|
| $V_{DD}$  | $V_{DD}$ supply voltage       | 2.97            | 3.3 | 3.63            | V    |
| $V_{DDA}$ | $V_{DDA}$ supply voltage      | 2.97            | 3.3 | 3.63            | V    |
| $V_{DDC}$ | $V_{DDC}$ supply voltage      | 1.08            | 1.2 | 1.32            | V    |
| $V_{IH}$  | GPIO high-level input voltage | $0.65 * V_{DD}$ | -   | $V_{DD}$        | V    |
| $V_{IL}$  | GPIO low-level input voltage  | 0               | -   | $0.35 * V_{DD}$ | V    |

**Table 24-2. Recommended DC Operating Conditions (continued)**

| Parameter | Parameter Name                                     | Min  | Nom | Max | Unit |
|-----------|----------------------------------------------------|------|-----|-----|------|
| $V_{HYS}$ | GPIO Input Hysteresis                              | 0.2  | -   | -   | V    |
| $V_{OH}$  | High-level output voltage                          | 2.4  | -   | -   | V    |
| $V_{OL}$  | Low-level output voltage                           | -    | -   | 0.4 | V    |
| $I_{OH}$  | High-level source current, $V_{OH}=2.4\text{ V}^a$ |      |     |     |      |
|           | 2-mA Drive                                         | -2.0 | -   | -   | mA   |
|           | 4-mA Drive                                         | -4.0 | -   | -   | mA   |
|           | 8-mA Drive                                         | -8.0 | -   | -   | mA   |
| $I_{OL}$  | Low-level sink current, $V_{OL}=0.4\text{ V}^a$    |      |     |     |      |
|           | 2-mA Drive                                         | 2.0  | -   | -   | mA   |
|           | 4-mA Drive                                         | 4.0  | -   | -   | mA   |
|           | 8-mA Drive                                         | 8.0  | -   | -   | mA   |
|           | 8-mA Drive, $V_{OL}=1.2\text{ V}$                  | 18.0 | -   | -   | mA   |

a.  $I_O$  specifications reflect the maximum current where the corresponding output voltage meets the  $V_{OH}/V_{OL}$  thresholds.  $I_O$  current can exceed these limits (subject to absolute maximum ratings).

**Table 24-3. GPIO Current Restrictions<sup>a</sup>**

| Parameter  | Parameter Name                                                | Min | Nom | Max | Unit |
|------------|---------------------------------------------------------------|-----|-----|-----|------|
| $I_{MAXL}$ | Cumulative maximum GPIO current per side, left <sup>b</sup>   | -   | -   | 30  | mA   |
| $I_{MAXB}$ | Cumulative maximum GPIO current per side, bottom <sup>b</sup> | -   | -   | 35  | mA   |
| $I_{MAXR}$ | Cumulative maximum GPIO current per side, right <sup>b</sup>  | -   | -   | 40  | mA   |
| $I_{MAXT}$ | Cumulative maximum GPIO current per side, top <sup>b</sup>    | -   | -   | 40  | mA   |

a. Based on design simulations, not tested in production.

b. Sum of sink and source current for GPIOs as shown in Table 24-4 on page 1324.

**Table 24-4. GPIO Package Side Assignments**

| Side   | GPIOs                                |
|--------|--------------------------------------|
| Left   | PB[6-7], PC[4-7], PD7, PE[0-3], PF4  |
| Bottom | PA[0-7], PF[0-3], PG5                |
| Right  | PB[0-3], PD[4-5], PG[0-4]            |
| Top    | PB[4-5], PC[0-3], PD[0-3,6], PE[4-5] |

## 24.3 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements.

**Figure 24-3. Load Conditions**

## 24.4 JTAG and Boundary Scan

Table 24-5. JTAG Characteristics

| Parameter No. | Parameter       | Parameter Name                                                            | Min | Nom         | Max | Unit |
|---------------|-----------------|---------------------------------------------------------------------------|-----|-------------|-----|------|
| J1            | $F_{TCK}$       | TCK operational clock frequency <sup>a</sup>                              | 0   | -           | 10  | MHz  |
| J2            | $T_{TCK}$       | TCK operational clock period                                              | 100 | -           | -   | ns   |
| J3            | $T_{TCK\_LOW}$  | TCK clock Low time                                                        | -   | $t_{TCK}/2$ | -   | ns   |
| J4            | $T_{TCK\_HIGH}$ | TCK clock High time                                                       | -   | $t_{TCK}/2$ | -   | ns   |
| J5            | $T_{TCK\_R}$    | TCK rise time                                                             | 0   | -           | 10  | ns   |
| J6            | $T_{TCK\_F}$    | TCK fall time                                                             | 0   | -           | 10  | ns   |
| J7            | $T_{TMS\_SU}$   | TMS setup time to TCK rise                                                | 8   | -           | -   | ns   |
| J8            | $T_{TMS\_HLD}$  | TMS hold time from TCK rise                                               | 4   | -           | -   | ns   |
| J9            | $T_{TDI\_SU}$   | TDI setup time to TCK rise                                                | 18  | -           | -   | ns   |
| J10           | $T_{TDI\_HLD}$  | TDI hold time from TCK rise                                               | 4   | -           | -   | ns   |
| J11           | $T_{TDO\_ZDV}$  | TCK fall to Data Valid from High-Z, 2-mA drive                            | -   | 13          | 35  | ns   |
|               |                 | TCK fall to Data Valid from High-Z, 4-mA drive                            |     | 9           | 26  | ns   |
|               |                 | TCK fall to Data Valid from High-Z, 8-mA drive                            |     | 8           | 26  | ns   |
|               |                 | TCK fall to Data Valid from High-Z, 8-mA drive with slew rate control     |     | 10          | 29  | ns   |
| J12           | $T_{TDO\_DV}$   | TCK fall to Data Valid from Data Valid, 2-mA drive                        | -   | 14          | 20  | ns   |
|               |                 | TCK fall to Data Valid from Data Valid, 4-mA drive                        |     | 10          | 26  | ns   |
|               |                 | TCK fall to Data Valid from Data Valid, 8-mA drive                        |     | 8           | 21  | ns   |
|               |                 | TCK fall to Data Valid from Data Valid, 8-mA drive with slew rate control |     | 10          | 26  | ns   |
| J13           | $T_{TDO\_DVZ}$  | TCK fall to High-Z from Data Valid, 2-mA drive                            | -   | 7           | 16  | ns   |
|               |                 | TCK fall to High-Z from Data Valid, 4-mA drive                            |     | 7           | 16  | ns   |
|               |                 | TCK fall to High-Z from Data Valid, 8-mA drive                            |     | 7           | 16  | ns   |
|               |                 | TCK fall to High-Z from Data Valid, 8-mA drive with slew rate control     |     | 8           | 19  | ns   |

a. A ratio of at least 8:1 must be kept between the system clock and TCK.

Figure 24-5. JTAG Test Access Port (TAP) Timing

## 24.5 Power and Brown-Out

Table 24-6. Power Characteristics

| Parameter No. | Parameter     | Parameter Name                           | Min | Nom  | Max            | Unit    |
|---------------|---------------|------------------------------------------|-----|------|----------------|---------|
| P1            | $T_{VDDRISE}$ | Supply voltage ( $V_{DD}$ ) rise time    | -   | -    | $\infty$       | ms      |
| P2            | $V_{TH}$      | Power-On Reset threshold (rising edge)   | 2.0 | 2.31 | 2.6            | V       |
|               |               | Power-On Reset threshold (falling edge)  | 2.0 | 2.27 | 2.6            | V       |
| P3            | $V_{BTH}$     | Brown-Out Reset threshold (rising edge)  | 2.8 | 2.92 | 3.1            | V       |
|               |               | Brown-Out Reset threshold (falling edge) | 2.8 | 2.90 | 3.1            | V       |
| P4            | $T_{POR}$     | Power-On Reset timeout                   | -   | -    | 500            | $\mu$ s |
| P5            | $T_{BOR}$     | Brown-Out Reset timeout                  | 1   | -    | - <sup>a</sup> | $\mu$ s |

a. After the minimum timeout, BOR stays active as long as the power supply is below  $V_{BTH}$ . The voltage level is checked every clock cycle after the initial countdown completes. BOR is deasserted on the next clock cycle after the BOR condition goes away.

## 24.6 Reset

Table 24-7. Reset Characteristics

| Parameter No. | Parameter   | Parameter Name                                                     | Min | Nom | Max            | Unit          |
|---------------|-------------|--------------------------------------------------------------------|-----|-----|----------------|---------------|
| R1            | $T_{IRHWR}$ | Internal reset timeout after hardware reset (RST pin) <sup>a</sup> | 20  | -   | - <sup>b</sup> | $\mu\text{s}$ |
| R2            | $T_{IRSWR}$ | Internal reset timeout after software-initiated system reset       | -   | 1   | -              | $\mu\text{s}$ |
| R3            | $T_{IRWDR}$ | Internal reset timeout after watchdog reset                        | -   | 1   | -              | $\mu\text{s}$ |
| R4            | $T_{IRMFR}$ | Internal reset timeout after MOSC failure reset                    | -   | 1   | -              | $\mu\text{s}$ |

**Table 24-7. Reset Characteristics (continued)**

| Parameter No. | Parameter | Parameter Name          | Min | Nom | Max | Unit |
|---------------|-----------|-------------------------|-----|-----|-----|------|
| R5            | $T_{MIN}$ | Minimum RST pulse width | 100 | -   | -   | ns   |

- a. When in Deep-Sleep mode with the IOSC as the clock source, the internal reset timeout after a hardware reset is  $30\ \mu\text{s}$  \* the Deep-sleep clock divider (DSDIVORIDE).
- b. After the minimum timeout, internal reset stays active as long as the RST pin is asserted, and is released when the RST pin is deasserted.

**Figure 24-8. External Reset Timing ( $\overline{\text{RST}}$ )****Figure 24-9. Software Reset Timing****Figure 24-10. Watchdog Reset Timing****Figure 24-11. MOSC Failure Reset Timing**

## 24.7 On-Chip Low Drop-Out (LDO) Regulator

**Table 24-8. LDO Regulator Characteristics**

| Parameter | Parameter Name                                                        | Min | Nom | Max | Unit          |
|-----------|-----------------------------------------------------------------------|-----|-----|-----|---------------|
| $C_{LDO}$ | External filter capacitor size for internal power supply <sup>a</sup> | 2.5 | -   | 4.0 | $\mu\text{F}$ |

**Table 24-8. LDO Regulator Characteristics (continued)**

| Parameter           | Parameter Name                                | Min  | Nom | Max  | Unit |
|---------------------|-----------------------------------------------|------|-----|------|------|
| ESR                 | Filter capacitor equivalent series resistance | 10   | -   | 100  | mΩ   |
| ESL                 | Filter capacitor equivalent series inductance | -    | -   | 0.5  | nH   |
| V <sub>LDO</sub>    | LDO output voltage                            | 1.08 | 1.2 | 1.32 | V    |
| I <sub>INRUSH</sub> | Inrush current                                | 50   | -   | 250  | mA   |

a. The capacitor should be connected as close as possible to pin 56.

## 24.8 Clocks

The following sections provide specifications on the various clock sources and mode.

### 24.8.1 PLL Specifications

The following tables provide specifications for using the PLL.

**Table 24-9. Phase Locked Loop (PLL) Characteristics**

| Parameter             | Parameter Name                                                                                                       | Min            | Nom | Max                      | Unit                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------|----------------|-----|--------------------------|-------------------------------|
| F <sub>REF_XTAL</sub> | Crystal reference                                                                                                    | 5 <sup>a</sup> | -   | 25                       | MHz                           |
| F <sub>REF_EXT</sub>  | External clock reference <sup>a</sup>                                                                                | 5 <sup>a</sup> | -   | 25                       | MHz                           |
| F <sub>PLL</sub>      | PLL frequency <sup>b</sup>                                                                                           | -              | 400 | -                        | MHz                           |
| T <sub>READY</sub>    | PLL lock time, enabling the PLL                                                                                      | -              | -   | 512 * (N+1) <sup>c</sup> | reference clocks <sup>d</sup> |
|                       | PLL lock time, changing the XTAL field in the <b>RCC/RCC2</b> register or changing the OSCSRC between MOSC and PIOSC | -              | -   | 128 * (N+1) <sup>c</sup> | reference clocks <sup>d</sup> |

a. If the PLL is not used, the minimum input frequency can be 4 MHz.

b. PLL frequency is automatically calculated by the hardware based on the XTAL field of the **RCC** register.

c. N is the value in the N field in the **PLLREQ1** register.

d. A reference clock is the clock period of the crystal being used, which can be MOSC or PIOSC. For example, a 16-MHz crystal connected to MOSC yields a reference clock of 62.5 ns.

Table 24-10 on page 1329 shows the actual frequency of the PLL based on the crystal frequency used (defined by the XTAL field in the **RCC** register).

**Table 24-10. Actual PLL Frequency**

| XTAL | Crystal Frequency (MHz) | MINT | MFRAC | Q   | N   | PLL Multiplier | PLL Frequency (MHz) | Error   |
|------|-------------------------|------|-------|-----|-----|----------------|---------------------|---------|
| 0x09 | 5.0                     | 0x50 | 0x0   | 0x0 | 0x0 | 80             | 400                 | -       |
| 0x0A | 5.12                    | 0x9C | 0x100 | 0x0 | 0x1 | 156.25         | 400                 | -       |
| 0x0B | 6.0                     | 0xC8 | 0x0   | 0x0 | 0x2 | 200            | 400                 | -       |
| 0x0C | 6.144                   | 0xC3 | 0x140 | 0x0 | 0x2 | 195.3125       | 400                 | -       |

## 24.8.2 PIOSC Specifications

Table 24-11. PIOSC Clock Characteristics

| Parameter            | Parameter Name                                                                                                           | Min | Nom    | Max | Unit |
|----------------------|--------------------------------------------------------------------------------------------------------------------------|-----|--------|-----|------|
| F <sub>PIOSC25</sub> | Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C                                     | -   | ±0.25% | ±1% | -    |
| F <sub>PIOSCT</sub>  | Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C, across specified temperature range | -   | -      | ±3% | -    |

## 24.8.3 Internal 30-kHz Oscillator Specifications

Table 24-12. 30-kHz Clock Characteristics

| Parameter              | Parameter Name                       | Min | Nom | Max | Unit |
|------------------------|--------------------------------------|-----|-----|-----|------|
| F <sub>IOSC30KHZ</sub> | Internal 30-KHz oscillator frequency | 10  | 30  | 90  | KHz  |

## 24.8.4 Main Oscillator Specifications

Table 24-13. Main Oscillator Input Characteristics

| Parameter                       | Parameter Name                                            | Min            | Nom | Max | Unit |
|---------------------------------|-----------------------------------------------------------|----------------|-----|-----|------|
| F <sub>MOSC</sub>               | Parallel resonance frequency                              | 4 <sup>a</sup> | -   | 25  | MHz  |
| C <sub>1</sub> , C <sub>2</sub> | External load capacitance on OSC0, OSC1 pins <sup>b</sup> | 12             | -   | 24  | pF   |
| C <sub>PKG</sub>                | Device package stray shunt capacitance <sup>b</sup>       | -              | 0.5 | -   | pF   |
| C <sub>PCB</sub>                | PCB stray shunt capacitance <sup>b</sup>                  | -              | 0.5 | -   | pF   |
| C <sub>0</sub>                  | Crystal shunt capacitance <sup>bc</sup>                   | -              | 4   | -   | pF   |
| C <sub>SHUNT</sub>              | Total shunt capacitance <sup>b</sup>                      | -              | -   | 4   | pF   |
| ESR                             | Crystal effective series resistance, 4 MHz <sup>dc</sup>  | -              | -   | 300 | Ω    |
|                                 | Crystal effective series resistance, 6 MHz <sup>dc</sup>  | -              | -   | 200 | Ω    |
|                                 | Crystal effective series resistance, 8 MHz <sup>dc</sup>  | -              | -   | 130 | Ω    |
|                                 | Crystal effective series resistance, 12 MHz <sup>dc</sup> | -              | -   | 120 | Ω    |
|                                 | Crystal effective series resistance, 16 MHz <sup>dc</sup> | -              | -   | 100 | Ω    |
|                                 | Crystal effective series resistance, 25 MHz <sup>dc</sup> | -              | -   | 50  | Ω    |

**Table 24-13. Main Oscillator Input Characteristics (continued)**

| Parameter                | Parameter Name                                                  | Min                    | Nom                | Max                    | Unit |
|--------------------------|-----------------------------------------------------------------|------------------------|--------------------|------------------------|------|
| DL                       | Oscillator output drive level <sup>e</sup>                      | -                      | OSC <sub>PWR</sub> | -                      | mW   |
| T <sub>START</sub>       | Oscillator startup time, when using a crystal <sup>f</sup>      | -                      | -                  | 18                     | ms   |
| V <sub>IH</sub>          | CMOS input high level, when using an external oscillator        | 0.65 * V <sub>DD</sub> | -                  | V <sub>DD</sub>        | V    |
| V <sub>IL</sub>          | CMOS input low level, when using an external oscillator         | GND                    | -                  | 0.35 * V <sub>DD</sub> | V    |
| V <sub>HYS</sub>         | CMOS input buffer hysteresis, when using an external oscillator | 150                    | -                  | -                      | mV   |
| DC <sub>HIBOSC_EXT</sub> | External clock reference duty cycle                             | 45                     | -                  | 55                     | %    |

a. 5 MHz is the minimum when using the PLL.

b. See information below table.

c. Crystal vendors can be contacted to confirm these specifications are met for a specific crystal part number if the vendors generic crystal datasheet show limits outside of these specifications.

d. Crystal ESR specified by crystal manufacturer.

e.  $OSC_{PWR} = (2 * \pi * F_P * C_L * 2.5)^2 * ESR / 2$ . An estimation of the typical power delivered to the crystal is based on the  $C_L$ ,  $F_P$  and ESR parameters of the crystal in the circuit as calculated by the  $OSC_{PWR}$  equation. Ensure that the value calculated for  $OSC_{PWR}$  does not exceed the crystal's drive-level maximum.

f. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

The load capacitors added on the board,  $C_1$  and  $C_2$ , should be chosen such that the following equation is satisfied (see Table 24-13 on page 1330 for typical values and Table 24-14 on page 1331 for detailed crystal parameter information).

- $C_L$  = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{SHUNT}$
- $C_{SHUNT} = C_0 + C_{PKG} + C_{PCB}$  (total shunt capacitance seen across OSC0, OSC1 crystal inputs)
- $C_{PKG}$ ,  $C_{PCB}$  = the mutual caps as measured across the OSC0, OSC1 pins excluding the crystal.
- $C_0$  = Shunt capacitance of crystal specified by the crystal manufacturer

**Table 24-14. Crystal Parameters**

| MFG | MFG Part#                 | Holder   | PKG Size<br>(mm x mm) | Freq (MHz) | Crystal Spec | Crystal Parameters |        |        |            |             |        | Recommended<br>Component<br>Values |         |           | WC DI(μW) |
|-----|---------------------------|----------|-----------------------|------------|--------------|--------------------|--------|--------|------------|-------------|--------|------------------------------------|---------|-----------|-----------|
|     |                           |          |                       |            |              | Typical Values     |        |        | Max Values |             |        |                                    |         |           |           |

**Table 24-15. Supported MOSC Crystal Frequencies (continued)**

| Value | Crystal Frequency (MHz) Not Using the PLL | Crystal Frequency (MHz) Using the PLL |
|-------|-------------------------------------------|---------------------------------------|
| 0x10  |                                           | 10.0 MHz (USB)                        |
| 0x11  |                                           | 12.0 MHz (USB)                        |
| 0x12  |                                           | 12.288 MHz                            |
| 0x13  |                                           | 13.56 MHz                             |
| 0x14  |                                           | 14.31818 MHz                          |
| 0x15  |                                           | 16.0 MHz (reset value)(USB)           |
| 0x16  |                                           | 16.384 MHz                            |
| 0x17  |                                           | 18.0 MHz (USB)                        |
| 0x18  |                                           | 20.0 MHz (USB)                        |
| 0x19  |                                           | 24.0 MHz (USB)                        |
| 0x1A  |                                           | 25.0 MHz (USB)                        |

a. Frequencies that may be used with the USB interface are indicated in the table.

## 24.8.5 System Clock Specification with ADC Operation

**Table 24-16. System Clock Characteristics with ADC Operation**

| Parameter           | Parameter Name                                                                               | Min     | Nom | Max     | Unit |
|---------------------|----------------------------------------------------------------------------------------------|---------|-----|---------|------|
| F <sub>sysadc</sub> | System clock frequency when the ADC module is operating (when PLL is bypassed). <sup>a</sup> | 15.9952 | 16  | 16.0048 | MHz  |

a. Clock frequency (plus jitter) must be stable inside specified range. ADC can be clocked from the PLL, directly from an external clock source, or from the PIOSC, as long as frequency absolute precision is inside specified range.

## 24.8.6 System Clock Specification with USB Operation

**Table 24-17. System Clock Characteristics with USB Operation**

| Parameter           | Parameter Name                                                                                                                          | Min | Nom | Max | Unit |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------|-----|-----|-----|------|
| F <sub>sysusb</sub> | System clock frequency when the USB module is operating (note that MOSC must be the clock source, either with or without using the PLL) | 20  | -   | -   | MHz  |

## 24.9 Sleep Modes

**Table 24-18. Sleep Modes AC Characteristics<sup>a</sup>**

| Parameter No | Parameter                | Parameter Name                                                                                                       | Min | Nom  | Max                | Unit          |
|--------------|--------------------------|----------------------------------------------------------------------------------------------------------------------|-----|------|--------------------|---------------|
| D1           | T <sub>WAKE_S</sub>      | Time to wake from interrupt in sleep mode <sup>b</sup>                                                               | -   | -    | 2                  | system clocks |
|              | T <sub>WAKE_DS</sub>     | Time to wake from interrupt in deep-sleep mode, using PIOSC for both Run mode and Deep-sleep mode <sup>b c</sup>     | -   | 1.25 | -                  | μs            |
|              |                          | Time to wake from interrupt in deep-sleep mode, using PIOSC for Run mode and IOSC for Deep-sleep mode <sup>b c</sup> | -   | 350  | -                  | μs            |
| D2           | T <sub>WAKE_PLL_DS</sub> | Time to wake from interrupt in deep-sleep mode when using the PLL <sup>b</sup>                                       | -   | -    | T <sub>READY</sub> | ms            |

a. Values in this table assume the IOSC is the clock source during sleep or deep-sleep mode.

b. Specified from registering the interrupt to first instruction.

c. If the main oscillator is used for run mode, add the main oscillator startup time,  $T_{START}$ .

## 24.10 Flash Memory and EEPROM

**Table 24-19. Flash Memory Characteristics**

| Parameter    | Parameter Name                                                        | Min     | Nom | Max | Unit   |
|--------------|-----------------------------------------------------------------------|---------|-----|-----|--------|
| $PE_{CYC}$   | Number of guaranteed program/erase cycles before failure <sup>a</sup> | 100,000 | -   | -   | cycles |
| $T_{RET}$    | Data retention, -40°C to +85°C                                        | 10      | -   | -   | years  |
| $T_{PROG64}$ | Program time for double-word-aligned 64 bits of data <sup>b</sup>     | 30      | 50  | 300 | μs     |
| $T_{ERASE}$  | Page erase time, <1k cycles endurance                                 | 2       | 25  | -   | ms     |
|              | Page erase time, 100k cycles endurance                                | -       | -   | 900 | ms     |
| $T_{ME}$     | Mass erase time, <1k cycles endurance                                 | 70      | 200 | -   | ms     |
|              | Mass erase time, 100k cycles endurance                                | -       | -   | 900 | ms     |

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

b. If programming fewer than 64 bits of data, the programming time is the same. For example, if only 32 bits of data need to be programmed, the other 32 bits are masked off.

**Table 24-20. EEPROM Characteristics<sup>a</sup>**

| Parameter   | Parameter Name                                                                                                                                     | Min     | Nom | Max  | Unit          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------|-----|------|---------------|
| $EPE_{CYC}$ | Number of guaranteed mass program/erase cycles of a single word before failure <sup>b</sup>                                                        | 500,000 | -   | -    | cycles        |
| $ET_{RET}$  | Data retention, -40°C to +85°C                                                                                                                     | 10      | -   | -    | years         |
| $ET_{PROG}$ | Program time for 32 bits of data - space available                                                                                                 | -       | 110 | 600  | μs            |
|             | Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer has space and less than 10% of EEPROM endurance used            | -       | 30  | -    | ms            |
|             | Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer has space and greater than 90% of EEPROM endurance used         | -       | -   | 900  | ms            |
|             | Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer requires an erase and less than 10% of EEPROM endurance used    | -       | 60  | -    | ms            |
|             | Program time for 32 bits of data - requires a copy to the copy buffer, copy buffer requires an erase and greater than 90% of EEPROM endurance used | -       | -   | 1800 | ms            |
| $ET_{READ}$ | Read access time                                                                                                                                   | -       | 4   | -    | system clocks |
| $ET_{ME}$   | Mass erase time, <1k cycles endurance                                                                                                              | 70      | 200 | -    | ms            |
|             | Mass erase time, 100k cycles endurance                                                                                                             | -       | -   | 900  | ms            |

a. Because the EEPROM operates as a background task and does not prevent the CPU from executing from Flash memory, the operation will complete within the maximum time specified provided the EEPROM operation is not stalled by a Flash memory program or erase operation.

b. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

## 24.11 Input/Output Characteristics

**Note:** All GPIOs are 5-V tolerant, except PB0 and PB1. See “Signal Description” on page 623 for more information on GPIO configuration.

Table 24-21. GPIO Module Characteristics<sup>ab</sup>

| Parameter           | Parameter Name                                                                                                                | Min | Nom  | Max               | Unit |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------|-----|------|-------------------|------|

|                     | GPIO fall time, 8-mA drive <sup>i</sup>                                                                                       |     | 8.6  | 11.2              | ns   |
|                     | GPIO fall time, 8-mA drive with slew rate control <sup>i</sup>                                                                |     | 11.3 | 12.9              | ns   |

a. V<sub>DD</sub> must be within the range specified in Table 24-2 on page 1323.

b. Leakage and Injection current characteristics specified in this table also apply to XOSC0 and XOSC1 inputs.

c. The leakage current is measured with V<sub>IN</sub> applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pullup/pulldown resistor is disabled.

d. To protect internal circuitry from over-voltage, the GPIOs have an internal voltage clamp that limits internal swings to V<sub>DD</sub> without affecting swing at the I/O pad. This internal clamp starts turning on while V<sub>DD</sub> < V<sub>IN</sub> < 4.0 V and causes a somewhat larger (but bounded) current draw. To save power, static input voltages between V<sub>DD</sub> and 4 V should be avoided.

e. Leakage current above maximum voltage (V<sub>IN</sub> = 5.5V) is not guaranteed, this condition is not allowed and can result in permanent damage to the device.

f. In this case, I<sub>LKG-</sub> is unbounded and must be limited to I<sub>INJ-</sub> using an external resistor.

g. Current injection is internally bounded for GPIOs, and maximum current into the pin is given by I<sub>LKG+</sub> for V<sub>DD</sub> < V<sub>IN</sub> < 5.5 V.

h. Time measured from 20% to 80% of V<sub>DD</sub>.

i. Time measured from 80% to 20% of V<sub>DD</sub>.

| $E_{\text{T}}$                                   | Total unadjusted error, over full input range <sup>j</sup>                      | -                 | $\pm 10.0$ | $\pm 30.0$                                       | LSB           |
| TEMPERATURE SENSOR                               |                                                                                 |                   |            |                                                  |               |
| $V_{\text{TSENS}}$                               | Temperature sensor voltage, junction temperature 25 °C                          | -                 | 1.633      | -                                                | V             |
| $S_{\text{TSENS}}$                               | Temperature sensor slope, ambient temperature -40 °C to 85 °C                   | -                 | -13.3      | -                                                | mV/°C         |
| $E_{\text{TSENS}}$                               | Temperature sensor accuracy, ambient temperature -40 °C to 85 °C <sup>k</sup>   | -                 | -          | $\pm 5$                                          | °C            |

a. At ambient temperature = -40 °C to 85 °C,  $V_{\text{REF+}} = 3.3\text{V}$ ,  $F_{\text{ADC}} = 16\text{ MHz}$  unless otherwise noted.

b. Two capacitors in parallel.

c. Internal reference is connected directly between  $V_{\text{DDA}}$  and GNDA ( $V_{\text{REFI}} = V_{\text{DDA}} - \text{GNDA}$ ). In this mode,  $E_{\text{O}}$ ,  $E_{\text{G}}$ ,  $E_{\text{T}}$ , and dynamic specifications are adversely affected due to internal voltage drop and noise on  $V_{\text{DDA}}$  and GNDA.

d.  $V_{\text{ADCIN}} = V_{\text{INP}} - V_{\text{INN}}$

e. With signal common mode as  $V_{\text{DDA}}/2$ .

f. This parameter is defined as the average of the differential inputs.

g. As shown in Figure 24-12 on page 1337,  $R_{\text{ADC}}$  is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.

h. See "System Clock Specification with ADC Operation" on page 1333 for full ADC clock frequency specification.

i. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.

- j. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.
- k. Note that this parameter does not include ADC error.

## 24.13 Synchronous Serial Interface (SSI)

**Table 24-23. SSI Characteristics**

| Parameter No. | Parameter       | Parameter Name                    | Min | Nom | Max  | Unit          |
|---------------|-----------------|-----------------------------------|-----|-----|------|---------------|
| S1            | $T_{CLK\_PER}$  | SSIClk cycle time <sup>a</sup>    | 40  | -   | -    | ns            |
| S2            | $T_{CLK\_HIGH}$ | SSIClk high time                  | -   | 0.5 | -    | t clk_per     |
| S3            | $T_{CLK\_LOW}$  | SSIClk low time                   | -   | 0.5 | -    | t clk_per     |
| S4            | $T_{CLKR}$      | SSIClk rise time <sup>b</sup>     | -   | 8.1 | 11.2 | ns            |
| S5            | $T_{CLKF}$      | SSIClk fall time <sup>b</sup>     | -   | 8.6 | 11.2 | ns            |
| S6            | $T_{DMD}$       | Data from master valid delay time | 0   | -   | 1    | system clocks |
| S7            | $T_{DMS}$       | Data from master setup time       | 1   | -   | -    | system clocks |
| S8            | $T_{DMH}$       | Data from master hold time        | 2   | -   | -    | system clocks |
| S9            | $T_{DSS}$       | Data from slave setup time        | 1   | -   | -    | system clocks |

**Table 24-23. SSI Characteristics (continued)**

| Parameter No. | Parameter | Parameter Name            | Min | Nom | Max | Unit          |
|---------------|-----------|---------------------------|-----|-----|-----|---------------|
| S10           | $T_{DSH}$ | Data from slave hold time | 2   | -   | -   | system clocks |

a. In master mode, the system clock must be at least twice as fast as the SSIClk; in slave mode, the system clock must be at least 6 times faster than the SSIClk.

b. Note that the delays shown are using 8-mA drive strength.

## 24.14 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

**Table 24-24. I<sup>2</sup>C Characteristics**

| Parameter No.   | Parameter         | Parameter Name                                                               | Min | Nom | Max          | Unit          |
|-----------------|-------------------|------------------------------------------------------------------------------|-----|-----|--------------|---------------|
| 11 <sup>a</sup> | T <sub>SCH</sub>  | Start condition hold time                                                    | 36  | -   | -            | system clocks |
| 12 <sup>a</sup> | T <sub>LP</sub>   | Clock Low period                                                             | 36  | -   | -            | system clocks |
| 13 <sup>b</sup> | T <sub>SRT</sub>  | I2CSCL/I2CSDA rise time (V <sub>IL</sub> = 0.5 V to V <sub>IH</sub> = 2.4 V) | -   | -   | (see note b) | ns            |
| 14 <sup>a</sup> | T <sub>DH</sub>   | Data hold time                                                               | 2   | -   | -            | system clocks |
| 15 <sup>c</sup> | T <sub>SFT</sub>  | I2CSCL/I2CSDA fall time (V <sub>IH</sub> = 2.4 V to V <sub>IL</sub> = 0.5 V) | -   | 9   | 10           | ns            |
| 16 <sup>a</sup> | T <sub>HT</sub>   | Clock High time                                                              | 24  | -   | -            | system clocks |
| 17 <sup>a</sup> | T <sub>DS</sub>   | Data setup time                                                              | 18  | -   | -            | system clocks |
| 18 <sup>a</sup> | T <sub>SCSR</sub> | Start condition setup time (for repeated start condition only)               | 36  | -   | -            | system clocks |
| 19 <sup>a</sup> | T <sub>SCS</sub>  | Stop condition setup time                                                    | 24  | -   | -            | system clocks |

a. Values depend on the value programmed into the TPR bit in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register; a TPR programmed for the maximum I2CSCL frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the I2CSCL Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.

b. Because I2CSCL and I2CSDA operate as open-drain-type signals, which the controller can only actively drive Low, the time I2CSCL or I2CSDA takes to reach a high level depends on external signal capacitance and pull-up resistor values.

c. Specified at a nominal 50 pF load.

Figure 24-16. I<sup>2</sup>C Timing

## 24.15 Universal Serial Bus (USB) Controller

The Stellaris<sup>®</sup> USB controller electrical specifications are compliant with the *Universal Serial Bus Specification Rev. 2.0* (full-speed and low-speed support) and the *On-The-Go Supplement to the USB 2.0 Specification Rev. 1.0*. Some components of the USB system are integrated within the LM4F231H5QR microcontroller and specific to the Stellaris microcontroller design.

## 24.16 Analog Comparator

Table 24-25. Analog Comparator Characteristics

| Parameter          | Parameter Name                                | Min  | Nom      | Max        | Unit    |
|--------------------|-----------------------------------------------|------|----------|------------|---------|
| $V_{INP}, V_{INN}$ | Input voltage range                           | GNDA | -        | $V_{DDA}$  | V       |
| $V_{CM}$           | Input common mode voltage range               | GNDA | -        | $V_{DDA}$  | V       |
| $V_{OS}$           | Input offset voltage                          | -    | $\pm 10$ | $\pm 25^a$ | mV      |
| $I_{INP}, I_{INN}$ | Input leakage current over full voltage range | -    | -        | 2.0        | $\mu A$ |
| $C_{MRR}$          | Common mode rejection ratio                   | -    | 50       | -          | dB      |
| $T_{RT}$           | Response time                                 | -    | -        | $1.0^b$    | $\mu s$ |
| $T_{MC}$           | Comparator mode change to Output Valid        | -    | -        | 10         | $\mu s$ |

a. Measured at  $V_{REF}=100$  mV.

b. Measured at external  $V_{REF}=100$  mV, input signal switching from 75 mV to 125 mV.

Table 24-26. Analog Comparator Voltage Reference Characteristics

| Parameter | Parameter Name               | Min | Nom             | Max            | Unit |
|-----------|------------------------------|-----|-----------------|----------------|------|
| $R_{HR}$  | Resolution in high range     | -   | $V_{DDA}/29.4$  | -              | V    |
| $R_{LR}$  | Resolution in low range      | -   | $V_{DDA}/22.12$ | -              | V    |
| $A_{HR}$  | Absolute accuracy high range | -   | -               | $\pm R_{HR}/2$ | V    |
| $A_{LR}$  | Absolute accuracy low range  | -   | -               | $\pm R_{LR}/2$ | V    |

**Table 24-29. Preliminary Current Consumption (continued)**

| Parameter                 | Parameter Name  | Conditions                                                                                                             | Nom  | Max | Unit |
|---------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------|------|-----|------|
| I <sub>DD_DEEPSLEEP</sub> | Deep-sleep mode | V <sub>DD</sub> = 3.3 V<br>V <sub>DDA</sub> = 3.3 V<br>Peripherals = All OFF<br>System Clock = IOS30KHZ<br>Temp = 25°C | 1.05 | -   | mA   |

- a. The value for I<sub>DDA\_RUN</sub> is included in the above values for I<sub>DD\_RUN</sub>.
- b. Note that if the MOSC is the source of the Run-mode system clock and is powered down in Sleep mode, wake time is increased by T<sub>MOSC\_SETTLE</sub>.

## B Ordering and Contact Information

### B.1 Ordering Information

**Table B-1. Part Ordering Information**

| Orderable Part Number | Description                                                                            |
|-----------------------|----------------------------------------------------------------------------------------|
| LM4F231H5QRFIG        | Stellaris® LM4F231H5QR Microcontroller Industrial Temperature 64-pin LQFP              |
| LM4F231H5QRFIGR       | Stellaris LM4F231H5QR Microcontroller Industrial Temperature 64-pin LQFP Tape-and-reel |

### B.2 Part Markings

The Stellaris microcontrollers are marked with an identifying number. This code contains the following information:

- The first and second lines indicate the part number, for example, LM4F232H5QDFIGA0. The second letter in the part number indicates the product status. An M indicates the part is fully qualified and released to production. An X, for example, LX4F232H5QDFIGA0, indicates the part is experimental and requires a waiver
- The third line contains internal tracking numbers.

### B.3 Kits

The Stellaris Family provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware and comprehensive documentation including hardware design files
- Evaluation Kits provide a low-cost and effective means of evaluating Stellaris microcontrollers before purchase
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box

See the website at [www.ti.com/stellaris](http://www.ti.com/stellaris) for the latest tools available, or ask your distributor.

## **B.4 Support Information**

For support on Stellaris products, contact the TI Worldwide Product Information Center nearest you:  
<http://www-k.ext.ti.com/sc/technical-support/product-information-centers.htm>.

## C Package Information

### C.1 64-Pin LQFP Package

#### C.1.1 Package Dimensions

Figure C-1. Stellaris LM4F231H5QR 64-Pin LQFP Package

MTQF008A – JANUARY 1995 – REVISED DECEMBER 1996

PM (S-PQFP-G64)

PLASTIC QUAD FLATPACK

- NOTES:
- A. All linear dimensions are in millimeters.
  - B. This drawing is subject to change without notice.
  - C. Falls within JEDEC MS-026
  - D. May also be thermally enhanced plastic with leads connected to the die pads.

<sup>(1)</sup> The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

<sup>(3)</sup> MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46C and to discontinue any product or service per JESD48B. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components which meet ISO/TS16949 requirements, mainly for automotive use. Components which have not been so designated are neither designed nor intended for automotive use; and TI will not be responsible for any failure of such components to meet such requirements.
