

# ANTREX Electronics

Electronic Components Sourcing Information

---

## Product Reference Information

**Part Number:** LX4F231H5QRFIGA3  
**Manufacturer:** Texas Instruments  
**Package:** 64-LQFP  
**Availability:** Please confirm with sales

## Contact Information

Email: [info@antrexco.com](mailto:info@antrexco.com)

WhatsApp: +86-186-8066-5326

Website: <https://antrexco.com>

## Quality & Trust

New & Original Components

Supplier verification and packaging condition review

CoC / RoHS / REACH documents available on request

Secure sourcing support for OEM / EMS projects

### Note:

This PDF includes an ANTREX product reference cover page.

The original manufacturer datasheet follows from the next page.

## List of Registers

|                                                                              |            |
|------------------------------------------------------------------------------|------------|
| <b>The Cortex-M4F Processor .....</b>                                        | <b>70</b>  |
| Register 1: Cortex General-Purpose Register 0 (R0) .....                     | 78         |
| Register 2: Cortex General-Purpose Register 1 (R1) .....                     | 78         |
| Register 3: Cortex General-Purpose Register 2 (R2) .....                     | 78         |
| Register 4: Cortex General-Purpose Register 3 (R3) .....                     | 78         |
| Register 5: Cortex General-Purpose Register 4 (R4) .....                     | 78         |
| Register 6: Cortex General-Purpose Register 5 (R5) .....                     | 78         |
| Register 7: Cortex General-Purpose Register 6 (R6) .....                     | 78         |
| Register 8: Cortex General-Purpose Register 7 (R7) .....                     | 78         |
| Register 9: Cortex General-Purpose Register 8 (R8) .....                     | 78         |
| Register 10: Cortex General-Purpose Register 9 (R9) .....                    | 78         |
| Register 11: Cortex General-Purpose Register 10 (R10) .....                  | 78         |
| Register 12: Cortex General-Purpose Register 11 (R11) .....                  | 78         |
| Register 13: Cortex General-Purpose Register 12 (R12) .....                  | 78         |
| Register 14: Stack Pointer (SP) .....                                        | 79         |
| Register 15: Link Register (LR) .....                                        | 80         |
| Register 16: Program Counter (PC) .....                                      | 81         |
| Register 17: Program Status Register (PSR) .....                             | 82         |
| Register 18: Priority Mask Register (PRIMASK) .....                          | 86         |
| Register 19: Fault Mask Register (FAULTMASK) .....                           | 87         |
| Register 20: Base Priority Mask Register (BASEPRI) .....                     | 88         |
| Register 21: Control Register (CONTROL) .....                                | 89         |
| Register 22: Floating-Point Status Control (FPSC) .....                      | 91         |
| <b>Cortex-M4 Peripherals .....</b>                                           | <b>123</b> |
| Register 1: SysTick Control and Status Register (STCTRL), offset 0x010 ..... | 139        |
| Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014 .....     | 141        |
| Register 3: SysTick Current Value Register (STCURRENT), offset 0x018 .....   | 142        |
| Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100 .....              | 143        |
| Register 5: Interrupt 32-63 Set Enable (EN1), offset 0x104 .....             | 143        |
| Register 6: Interrupt 64-95 Set Enable (EN2), offset 0x108 .....             | 143        |
| Register 7: Interrupt 96-127 Set Enable (EN3), offset 0x10C .....            | 143        |
| Register 8: Interrupt 128-138 Set Enable (EN4), offset 0x110 .....           | 144        |
| Register 9: Interrupt 0-31 Clear Enable (DIS0), offset 0x180 .....           | 145        |
| Register 10: Interrupt 32-63 Clear Enable (DIS1), offset 0x184 .....         | 145        |
| Register 11: Interrupt 64-95 Clear Enable (DIS2), offset 0x188 .....         | 145        |
| Register 12: Interrupt 96-127 Clear Enable (DIS3), offset 0x18C .....        | 145        |
| Register 13: Interrupt 128-138 Clear Enable (DIS4), offset 0x190 .....       | 146        |
| Register 14: Interrupt 0-31 Set Pending (PEND0), offset 0x200 .....          | 147        |
| Register 15: Interrupt 32-63 Set Pending (PEND1), offset 0x204 .....         | 147        |
| Register 16: Interrupt 64-95 Set Pending (PEND2), offset 0x208 .....         | 147        |
| Register 17: Interrupt 96-127 Set Pending (PEND3), offset 0x20C .....        | 147        |
| Register 18: Interrupt 128-138 Set Pending (PEND4), offset 0x210 .....       | 148        |
| Register 19: Interrupt 0-31 Clear Pending (UNPEND0), offset 0x280 .....      | 149        |
| Register 20: Interrupt 32-63 Clear Pending (UNPEND1), offset 0x284 .....     | 149        |
| Register 21: Interrupt 64-95 Clear Pending (UNPEND2), offset 0x288 .....     | 149        |

|              |                                                                     |     |
|--------------|---------------------------------------------------------------------|-----|
| Register 22: | Interrupt 96-127 Clear Pending (UNPEND3), offset 0x28C .....        | 149 |
| Register 23: | Interrupt 128-138 Clear Pending (UNPEND4), offset 0x290 .....       | 150 |
| Register 24: | Interrupt 0-31 Active Bit (ACTIVE0), offset 0x300 .....             | 151 |
| Register 25: | Interrupt 32-63 Active Bit (ACTIVE1), offset 0x304 .....            | 151 |
| Register 26: | Interrupt 64-95 Active Bit (ACTIVE2), offset 0x308 .....            | 151 |
| Register 27: | Interrupt 96-127 Active Bit (ACTIVE3), offset 0x30C .....           | 151 |
| Register 28: | Interrupt 128-138 Active Bit (ACTIVE4), offset 0x310 .....          | 152 |
| Register 29: | Interrupt 0-3 Priority (PRI0), offset 0x400 .....                   | 153 |
| Register 30: | Interrupt 4-7 Priority (PRI1), offset 0x404 .....                   | 153 |
| Register 31: | Interrupt 8-11 Priority (PRI2), offset 0x408 .....                  | 153 |
| Register 32: | Interrupt 12-15 Priority (PRI3), offset 0x40C .....                 | 153 |
| Register 33: | Interrupt 16-19 Priority (PRI4), offset 0x410 .....                 | 153 |
| Register 34: | Interrupt 20-23 Priority (PRI5), offset 0x414 .....                 | 153 |
| Register 35: | Interrupt 24-27 Priority (PRI6), offset 0x418 .....                 | 153 |
| Register 36: | Interrupt 28-31 Priority (PRI7), offset 0x41C .....                 | 153 |
| Register 37: | Interrupt 32-35 Priority (PRI8), offset 0x420 .....                 | 153 |
| Register 38: | Interrupt 36-39 Priority (PRI9), offset 0x424 .....                 | 153 |
| Register 39: | Interrupt 40-43 Priority (PRI10), offset 0x428 .....                | 153 |
| Register 40: | Interrupt 44-47 Priority (PRI11), offset 0x42C .....                | 153 |
| Register 41: | Interrupt 48-51 Priority (PRI12), offset 0x430 .....                | 153 |
| Register 42: | Interrupt 52-55 Priority (PRI13), offset 0x434 .....                | 153 |
| Register 43: | Interrupt 56-59 Priority (PRI14), offset 0x438 .....                | 153 |
| Register 44: | Interrupt 60-63 Priority (PRI15), offset 0x43C .....                | 153 |
| Register 45: | Interrupt 64-67 Priority (PRI16), offset 0x440 .....                | 155 |
| Register 46: | Interrupt 68-71 Priority (PRI17), offset 0x444 .....                | 155 |
| Register 47: | Interrupt 72-75 Priority (PRI18), offset 0x448 .....                | 155 |
| Register 48: | Interrupt 76-79 Priority (PRI19), offset 0x44C .....                | 155 |
| Register 49: | Interrupt 80-83 Priority (PRI20), offset 0x450 .....                | 155 |
| Register 50: | Interrupt 84-87 Priority (PRI21), offset 0x454 .....                | 155 |
| Register 51: | Interrupt 88-91 Priority (PRI22), offset 0x458 .....                | 155 |
| Register 52: | Interrupt 92-95 Priority (PRI23), offset 0x45C .....                | 155 |
| Register 53: | Interrupt 96-99 Priority (PRI24), offset 0x460 .....                | 155 |
| Register 54: | Interrupt 100-103 Priority (PRI25), offset 0x464 .....              | 155 |
| Register 55: | Interrupt 104-107 Priority (PRI26), offset 0x468 .....              | 155 |
| Register 56: | Interrupt 108-111 Priority (PRI27), offset 0x46C .....              | 155 |
| Register 57: | Interrupt 112-115 Priority (PRI28), offset 0x470 .....              | 155 |
| Register 58: | Interrupt 116-119 Priority (PRI29), offset 0x474 .....              | 155 |
| Register 59: | Interrupt 120-123 Priority (PRI30), offset 0x478 .....              | 155 |
| Register 60: | Interrupt 124-127 Priority (PRI31), offset 0x47C .....              | 155 |
| Register 61: | Interrupt 128-131 Priority (PRI32), offset 0x480 .....              | 155 |
| Register 62: | Interrupt 132-135 Priority (PRI33), offset 0x484 .....              | 155 |
| Register 63: | Interrupt 136-138 Priority (PRI34), offset 0x488 .....              | 155 |
| Register 64: | Software Trigger Interrupt (SWTRIG), offset 0xF00 .....             | 157 |
| Register 65: | Auxiliary Control (ACTLR), offset 0x008 .....                       | 158 |
| Register 66: | CPU ID Base (CPUID), offset 0xD00 .....                             | 160 |
| Register 67: | Interrupt Control and State (INTCTRL), offset 0xD04 .....           | 161 |
| Register 68: | Vector Table Offset (VTABLE), offset 0xD08 .....                    | 164 |
| Register 69: | Application Interrupt and Reset Control (APINT), offset 0xD0C ..... | 165 |

|                             |                                                                                  |     |
|-----------------------------|----------------------------------------------------------------------------------|-----|
| Register 70:                | System Control (SYSCTRL), offset 0xD10 .....                                     | 167 |
| Register 71:                | Configuration and Control (CFGCTRL), offset 0xD14 .....                          | 169 |
| Register 72:                | System Handler Priority 1 (SYSPRI1), offset 0xD18 .....                          | 171 |
| Register 73:                | System Handler Priority 2 (SYSPRI2), offset 0xD1C .....                          | 172 |
| Register 74:                | System Handler Priority 3 (SYSPRI3), offset 0xD20 .....                          | 173 |
| Register 75:                | System Handler Control and State (SYSHNDCTRL), offset 0xD24 .....                | 174 |
| Register 76:                | Configurable Fault Status (FAULTSTAT), offset 0xD28 .....                        | 178 |
| Register 77:                | Hard Fault Status (HFAULTSTAT), offset 0xD2C .....                               | 184 |
| Register 78:                | Memory Management Fault Address (MMADDR), offset 0xD34 .....                     | 185 |
| Register 79:                | Bus Fault Address (FAULTADDR), offset 0xD38 .....                                | 186 |
| Register 80:                | MPU Type (MPUTYPE), offset 0xD90 .....                                           | 187 |
| Register 81:                | MPU Control (MPUCTRL), offset 0xD94 .....                                        | 188 |
| Register 82:                | MPU Region Number (MPUNUMBER), offset 0xD98 .....                                | 190 |
| Register 83:                | MPU Region Base Address (MPUBASE), offset 0xD9C .....                            | 191 |
| Register 84:                | MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4 .....                   | 191 |
| Register 85:                | MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC .....                   | 191 |
| Register 86:                | MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4 .....                   | 191 |
| Register 87:                | MPU Region Attribute and Size (MPUATTR), offset 0xDA0 .....                      | 193 |
| Register 88:                | MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8 .....             | 193 |
| Register 89:                | MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0 .....             | 193 |
| Register 90:                | MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8 .....             | 193 |
| Register 91:                | Coprocessor Access Control (CPAC), offset 0xD88 .....                            | 196 |
| Register 92:                | Floating-Point Context Control (FPCC), offset 0xF34 .....                        | 197 |
| Register 93:                | Floating-Point Context Address (FPCA), offset 0xF38 .....                        | 199 |
| Register 94:                | Floating-Point Default Status Control (FPDSC), offset 0xF3C .....                | 200 |
| <b>System Control .....</b> | <b>213</b>                                                                       |     |
| Register 1:                 | Device Identification 0 (DID0), offset 0x000 .....                               | 236 |
| Register 2:                 | Device Identification 1 (DID1), offset 0x004 .....                               | 238 |
| Register 3:                 | Brown-Out Reset Control (PBORCTL), offset 0x030 .....                            | 240 |
| Register 4:                 | Raw Interrupt Status (RIS), offset 0x050 .....                                   | 241 |
| Register 5:                 | Interrupt Mask Control (IMC), offset 0x054 .....                                 | 243 |
| Register 6:                 | Masked Interrupt Status and Clear (MISC), offset 0x058 .....                     | 245 |
| Register 7:                 | Reset Cause (RESC), offset 0x05C .....                                           | 247 |
| Register 8:                 | Run-Mode Clock Configuration (RCC), offset 0x060 .....                           | 249 |
| Register 9:                 | GPIO High-Performance Bus Control (GPIOHBCTL), offset 0x06C .....                | 254 |
| Register 10:                | Run-Mode Clock Configuration 2 (RCC2), offset 0x070 .....                        | 256 |
| Register 11:                | Main Oscillator Control (MOSCCTL), offset 0x07C .....                            | 259 |
| Register 12:                | Deep Sleep Clock Configuration (DSLPCCLKCFG), offset 0x144 .....                 | 260 |
| Register 13:                | System Properties (SYSPROP), offset 0x14C .....                                  | 262 |
| Register 14:                | Precision Internal Oscillator Calibration (PIOSCCAL), offset 0x150 .....         | 263 |
| Register 15:                | PLL Frequency 0 (PLLFREQ0), offset 0x160 .....                                   | 264 |
| Register 16:                | PLL Frequency 1 (PLLFREQ1), offset 0x164 .....                                   | 265 |
| Register 17:                | PLL Status (PLLSTAT), offset 0x168 .....                                         | 266 |
| Register 18:                | Watchdog Timer Peripheral Present (PPWD), offset 0x300 .....                     | 267 |
| Register 19:                | 16/32-Bit General-Purpose Timer Peripheral Present (PPTIMER), offset 0x304 ..... | 268 |
| Register 20:                | General-Purpose Input/Output Peripheral Present (PPGPIO), offset 0x308 .....     | 270 |
| Register 21:                | Micro Direct Memory Access Peripheral Present (PPDMA), offset 0x30C .....        | 273 |
| Register 22:                | Hibernation Peripheral Present (PPHIB), offset 0x314 .....                       | 274 |

|              |                                                                                                          |     |
|--------------|----------------------------------------------------------------------------------------------------------|-----|
| Register 23: | Universal Asynchronous Receiver/Transmitter Peripheral Present (PPUART), offset 0x318 .....              | 275 |
| Register 24: | Synchronous Serial Interface Peripheral Present (PPSSI), offset 0x31C .....                              | 277 |
| Register 25: | Inter-Integrated Circuit Peripheral Present (PPI2C), offset 0x320 .....                                  | 279 |
| Register 26: | Universal Serial Bus Peripheral Present (PPUSB), offset 0x328 .....                                      | 281 |
| Register 27: | Controller Area Network Peripheral Present (PPCAN), offset 0x334 .....                                   | 282 |
| Register 28: | Analog-to-Digital Converter Peripheral Present (PPADC), offset 0x338 .....                               | 283 |
| Register 29: | Analog Comparator Peripheral Present (PPACMP), offset 0x33C .....                                        | 284 |
| Register 30: | Pulse Width Modulator Peripheral Present (PPPWM), offset 0x340 .....                                     | 285 |
| Register 31: | Quadrature Encoder Interface Peripheral Present (PPQEI), offset 0x344 .....                              | 286 |
| Register 32: | EEPROM Peripheral Present (PPEEPROM), offset 0x358 .....                                                 | 287 |
| Register 33: | 32/64-Bit Wide General-Purpose Timer Peripheral Present (PPWTIMER), offset 0x35C .....                   | 288 |
| Register 34: | Watchdog Timer Software Reset (SRWD), offset 0x500 .....                                                 | 290 |
| Register 35: | 16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504 .....                             | 292 |
| Register 36: | General-Purpose Input/Output Software Reset (SRGPIO), offset 0x508 .....                                 | 294 |
| Register 37: | Micro Direct Memory Access Software Reset (SRDMA), offset 0x50C .....                                    | 296 |
| Register 38: | Universal Asynchronous Receiver/Transmitter Software Reset (SRUART), offset 0x518 ....                   | 297 |
| Register 39: | Synchronous Serial Interface Software Reset (SRSSI), offset 0x51C .....                                  | 299 |
| Register 40: | Inter-Integrated Circuit Software Reset (SRI2C), offset 0x520 .....                                      | 301 |
| Register 41: | Universal Serial Bus Software Reset (SRUSB), offset 0x528 .....                                          | 303 |
| Register 42: | Controller Area Network Software Reset (SRCAN), offset 0x534 .....                                       | 304 |
| Register 43: | Analog-to-Digital Converter Software Reset (SRADC), offset 0x538 .....                                   | 306 |
| Register 44: | Analog Comparator Software Reset (SRACMP), offset 0x53C .....                                            | 308 |
| Register 45: | Pulse Width Modulator Software Reset (SRPWM), offset 0x540 .....                                         | 309 |
| Register 46: | Quadrature Encoder Interface Software Reset (SRQEI), offset 0x544 .....                                  | 311 |
| Register 47: | EEPROM Software Reset (SREEEPROM), offset 0x558 .....                                                    | 313 |
| Register 48: | 32/64-Bit Wide General-Purpose Timer Software Reset (SRWTIMER), offset 0x55C .....                       | 314 |
| Register 49: | Watchdog Timer Run Mode Clock Gating Control (RCGCWD), offset 0x600 .....                                | 316 |
| Register 50: | 16/32-Bit General-Purpose Timer Run Mode Clock Gating Control (RCGCTIMER), offset 0x604 .....            | 317 |
| Register 51: | General-Purpose Input/Output Run Mode Clock Gating Control (RCGCGPIO), offset 0x608 .....                | 319 |
| Register 52: | Micro Direct Memory Access Run Mode Clock Gating Control (RCGCDMA), offset 0x60C .....                   | 321 |
| Register 53: | Universal Asynchronous Receiver/Transmitter Run Mode Clock Gating Control (RCGCUART), offset 0x618 ..... | 322 |
| Register 54: | Synchronous Serial Interface Run Mode Clock Gating Control (RCGCSSI), offset 0x61C .....                 | 324 |
| Register 55: | Inter-Integrated Circuit Run Mode Clock Gating Control (RCGCI2C), offset 0x620 .....                     | 326 |
| Register 56: | Universal Serial Bus Run Mode Clock Gating Control (RCGCUSB), offset 0x628 .....                         | 328 |
| Register 57: | Controller Area Network Run Mode Clock Gating Control (RCGCCAN), offset 0x634 .....                      | 329 |
| Register 58: | Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC), offset 0x638 ....                   | 330 |
| Register 59: | Analog Comparator Run Mode Clock Gating Control (RCGCACMP), offset 0x63C .....                           | 331 |
| Register 60: | Pulse Width Modulator Run Mode Clock Gating Control (RCGCPWM), offset 0x640 .....                        | 332 |
| Register 61: | Quadrature Encoder Interface Run Mode Clock Gating Control (RCGCQEI), offset 0x644 .....                 | 333 |
| Register 62: | EEPROM Run Mode Clock Gating Control (RCGCEEPROM), offset 0x658 .....                                    | 334 |
| Register 63: | 32/64-Bit Wide General-Purpose Timer Run Mode Clock Gating Control (RCGCWTIMER), offset 0x65C .....      | 335 |

|              |                                                                                                                 |     |
|--------------|-----------------------------------------------------------------------------------------------------------------|-----|
| Register 64: | Watchdog Timer Sleep Mode Clock Gating Control (SCGCWD), offset 0x700 .....                                     | 337 |
| Register 65: | 16/32-Bit General-Purpose Timer Sleep Mode Clock Gating Control (SCGCTIMER), offset 0x704 .....                 | 338 |
| Register 66: | General-Purpose Input/Output Sleep Mode Clock Gating Control (SCGCGPIO), offset 0x708 .....                     | 340 |
| Register 67: | Micro Direct Memory Access Sleep Mode Clock Gating Control (SCGCDMA), offset 0x70C .....                        | 342 |
| Register 68: | Universal Asynchronous Receiver/Transmitter Sleep Mode Clock Gating Control (SCGCUART), offset 0x718 .....      | 343 |
| Register 69: | Synchronous Serial Interface Sleep Mode Clock Gating Control (SCGCSSI), offset 0x71C .....                      | 345 |
| Register 70: | Inter-Integrated Circuit Sleep Mode Clock Gating Control (SCGCI2C), offset 0x720 .....                          | 347 |
| Register 71: | Universal Serial Bus Sleep Mode Clock Gating Control (SCGUSB), offset 0x728 .....                               | 349 |
| Register 72: | Controller Area Network Sleep Mode Clock Gating Control (SCGCCAN), offset 0x734 .....                           | 350 |
| Register 73: | Analog-to-Digital Converter Sleep Mode Clock Gating Control (SCGCADC), offset 0x738 .....                       | 351 |
| Register 74: | Analog Comparator Sleep Mode Clock Gating Control (SCGCACMP), offset 0x73C .....                                | 352 |
| Register 75: | Pulse Width Modulator Sleep Mode Clock Gating Control (SCGCPWM), offset 0x740 .....                             | 353 |
| Register 76: | Quadrature Encoder Interface Sleep Mode Clock Gating Control (SCGCQEI), offset 0x744 .....                      | 354 |
| Register 77: | EEPROM Sleep Mode Clock Gating Control (SCGCEEPROM), offset 0x758 .....                                         | 355 |
| Register 78: | 32/64-Bit Wide General-Purpose Timer Sleep Mode Clock Gating Control (SCGCWTIMER), offset 0x75C .....           | 356 |
| Register 79: | Watchdog Timer Deep-Sleep Mode Clock Gating Control (DCGCWD), offset 0x800 .....                                | 358 |
| Register 80: | 16/32-Bit General-Purpose Timer Deep-Sleep Mode Clock Gating Control (DCGCTIMER), offset 0x804 .....            | 359 |
| Register 81: | General-Purpose Input/Output Deep-Sleep Mode Clock Gating Control (DCGCGPIO), offset 0x808 .....                | 361 |
| Register 82: | Micro Direct Memory Access Deep-Sleep Mode Clock Gating Control (DCGCDMA), offset 0x80C .....                   | 363 |
| Register 83: | Universal Asynchronous Receiver/Transmitter Deep-Sleep Mode Clock Gating Control (DCGCUART), offset 0x818 ..... | 364 |
| Register 84: | Synchronous Serial Interface Deep-Sleep Mode Clock Gating Control (DCGCSSI), offset 0x81C .....                 | 366 |
| Register 85: | Inter-Integrated Circuit Deep-Sleep Mode Clock Gating Control (DCGCI2C), offset 0x820 .....                     | 368 |
| Register 86: | Universal Serial Bus Deep-Sleep Mode Clock Gating Control (DCGUSB), offset 0x828 .....                          | 370 |
| Register 87: | Controller Area Network Deep-Sleep Mode Clock Gating Control (DCGCCAN), offset 0x834 .....                      | 371 |
| Register 88: | Analog-to-Digital Converter Deep-Sleep Mode Clock Gating Control (DCGCADC), offset 0x838 .....                  | 372 |
| Register 89: | Analog Comparator Deep-Sleep Mode Clock Gating Control (DCGCACMP), offset 0x83C .....                           | 373 |
| Register 90: | Pulse Width Modulator Deep-Sleep Mode Clock Gating Control (DCGCPWM), offset 0x840 .....                        | 374 |
| Register 91: | Quadrature Encoder Interface Deep-Sleep Mode Clock Gating Control (DCGCQEI), offset 0x844 .....                 | 375 |
| Register 92: | EEPROM Deep-Sleep Mode Clock Gating Control (DCGCEEPROM), offset 0x858 .....                                    | 376 |

|               |                                                                                                            |     |

| Register 106: | Quadrature Encoder Interface Power Control (PCQEI), offset 0x944 .....                                     | 405 |
| Register 107: | EEPROM Power Control (PCEEPROM), offset 0x958 .....                                                        | 407 |
| Register 108: | 32/64-Bit Wide General-Purpose Timer Power Control (PCWTIMER), offset 0x95C .....                          | 408 |
| Register 109: | Watchdog Timer Peripheral Ready (PRWD), offset 0xA00 .....                                                 | 411 |
| Register 110: | 16/32-Bit General-Purpose Timer Peripheral Ready (PRTIMER), offset 0xA04 .....                             | 412 |
| Register 111: | General-Purpose Input/Output Peripheral Ready (PRGPIO), offset 0xA08 .....                                 | 414 |
| Register 112: | Micro Direct Memory Access Peripheral Ready (PRDMA), offset 0xA0C .....                                    | 416 |
| Register 113: | Universal Asynchronous Receiver/Transmitter Peripheral Ready (PRUART), offset 0xA18 .....                  | 417 |
| Register 114: | Synchronous Serial Interface Peripheral Ready (PRSSI), offset 0xA1C .....                                  | 419 |
| Register 115: | Inter-Integrated Circuit Peripheral Ready (PRI2C), offset 0xA20 .....                                      | 421 |
| Register 116: | Universal Serial Bus Peripheral Ready (PRUSB), offset 0xA28 .....                                          | 423 |
| Register 117: | Controller Area Network Peripheral Ready (PRCAN), offset 0xA34 .....                                       | 424 |
| Register 118: | Analog-to-Digital Converter Peripheral Ready (PRADC), offset 0xA38 .....                                   | 425 |
| Register 119: | Analog Comparator Peripheral Ready (PRACMP), offset 0xA3C .....                                            | 426 |
| Register 120: | Pulse Width Modulator Peripheral Ready (PRPWM), offset 0xA40 .....                                         | 427 |
| Register 121: | Quadrature Encoder Interface Peripheral Ready (PRQEI), offset 0xA44 .....                                  | 428 |
| Register 122: | EEPROM Peripheral Ready (PREEPROM), offset 0xA58 .....                                                     | 429 |
| Register 123: | 32/64-Bit Wide General-Purpose Timer Peripheral Ready (PRWTIMER), offset 0xA5C .....                       | 430 |
| Register 124: | Device Capabilities 0 (DC0), offset 0x008 .....                                                            | 432 |
| Register 125: | Device Capabilities 1 (DC1), offset 0x010 .....                                                            | 434 |
| Register 126: | Device Capabilities 2 (DC2), offset 0x014 .....                                                            | 437 |
| Register 127: | Device Capabilities 3 (DC3), offset 0x018 .....                                                            | 440 |
| Register 128: | Device Capabilities 4 (DC4), offset 0x01C .....                                                            | 444 |
| Register 129: | Device Capabilities 5 (DC5), offset 0x020 .....                                                            | 447 |
| Register 130: | Device Capabilities 6 (DC6), offset 0x024 .....                                                            | 449 |
| Register 131: | Device Capabilities 7 (DC7), offset 0x028 .....                                                            | 450 |
| Register 132: | Device Capabilities 8 (DC8), offset 0x02C .....                                                            | 453 |
| Register 133: | Software Reset Control 0 (SRCR0), offset 0x040 .....                                                       | 456 |
| Register 134: | Software Reset Control 1 (SRCR1), offset 0x044 .....                                                       | 458 |
| Register 135: | Software Reset Control 2 (SRCR2), offset 0x048 .....                                                       | 461 |
| Register 136: | Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100 .....                                       | 463 |
| Register 137: | Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104 .....                                       | 467 |
| Register 138: | Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108 .....                                       | 471 |

|                                                                                              |            |
|----------------------------------------------------------------------------------------------|------------|
| Register 139: Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110 .....         | 474        |
| Register 140: Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114 .....         | 477        |
| Register 141: Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118 .....         | 480        |
| Register 142: Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120 .....    | 482        |
| Register 143: Deep-Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124 .....    | 485        |
| Register 144: Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128 .....    | 488        |
| Register 145: Device Capabilities 9 (DC9), offset 0x190 .....                                | 490        |
| Register 146: Non-Volatile Memory Information (NVMSTAT), offset 0x1A0 .....                  | 492        |
| <b>System Exception Module .....</b>                                                         | <b>493</b> |
| Register 1: System Exception Raw Interrupt Status (SYSEXCRI), offset 0x000 .....             | 494        |
| Register 2: System Exception Interrupt Mask (SYSEXCIM), offset 0x004 .....                   | 496        |
| Register 3: System Exception Masked Interrupt Status (SYSEXCMI), offset 0x008 .....          | 498        |
| Register 4: System Exception Interrupt Clear (SYSEXCIC), offset 0x00C .....                  | 500        |
| <b>Internal Memory .....</b>                                                                 | <b>501</b> |
| Register 1: Flash Memory Address (FMA), offset 0x000 .....                                   | 517        |
| Register 2: Flash Memory Data (FMD), offset 0x004 .....                                      | 518        |
| Register 3: Flash Memory Control (FMC), offset 0x008 .....                                   | 519        |
| Register 4: Flash Controller Raw Interrupt Status (FCRIS), offset 0x00C .....                | 521        |
| Register 5: Flash Controller Interrupt Mask (FCIM), offset 0x010 .....                       | 524        |
| Register 6: Flash Controller Masked Interrupt Status and Clear (FCMISC), offset 0x014 .....  | 526        |
| Register 7: Flash Memory Control 2 (FMC2), offset 0x020 .....                                | 529        |
| Register 8: Flash Write Buffer Valid (FWBVAL), offset 0x030 .....                            | 530        |
| Register 9: Flash Write Buffer n (FWBn), offset 0x100 - 0x17C .....                          | 531        |
| Register 10: Flash Size (FSIZE), offset 0xFC0 .....                                          | 532        |
| Register 11: SRAM Size (SSIZE), offset 0xFC4 .....                                           | 533        |
| Register 12: ROM Software Map (ROMSWMAP), offset 0xFCC .....                                 | 534        |
| Register 13: EEPROM Size Information (EESIZE), offset 0x000 .....                            | 535        |
| Register 14: EEPROM Current Block (EEBLOCK), offset 0x004 .....                              | 536        |
| Register 15: EEPROM Current Offset (EEOFFSET), offset 0x008 .....                            | 537        |
| Register 16: EEPROM Read-Write (EERDWR), offset 0x010 .....                                  | 538        |
| Register 17: EEPROM Read-Write with Increment (EERDWRINC), offset 0x014 .....                | 539        |
| Register 18: EEPROM Done Status (EEDONE), offset 0x018 .....                                 | 540        |
| Register 19: EEPROM Support Control and Status (EESUPP), offset 0x01C .....                  | 542        |
| Register 20: EEPROM Unlock (EEUNLOCK), offset 0x020 .....                                    | 544        |
| Register 21: EEPROM Protection (EEPROT), offset 0x030 .....                                  | 545        |
| Register 22: EEPROM Password (EEPASS0), offset 0x034 .....                                   | 546        |
| Register 23: EEPROM Password (EEPASS1), offset 0x038 .....                                   | 546        |
| Register 24: EEPROM Password (EEPASS2), offset 0x03C .....                                   | 546        |
| Register 25: EEPROM Interrupt (EEINT), offset 0x040 .....                                    | 547        |
| Register 26: EEPROM Block Hide (EEHIDE), offset 0x050 .....                                  | 548        |
| Register 27: EEPROM Debug Mass Erase (EEDBGME), offset 0x080 .....                           | 549        |
| Register 28: EEPROM Peripheral Properties (EEPROMPP), offset 0xFC0 .....                     | 550        |
| Register 29: ROM Control (RMCTL), offset 0x0F0 .....                                         | 551        |
| Register 30: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200 .....    | 552        |
| Register 31: Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204 .....              | 552        |
| Register 32: Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208 .....              | 552        |
| Register 33: Flash Memory Protection Read Enable 3 (FMPRE3), offset 0x20C .....              | 552        |
| Register 34: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400 ..... | 553        |

| Register 5: Analog Comparator Status 0 (ACSTAT0), offset 0x020 .....                                | 1185        |
| Register 6: Analog Comparator Status 1 (ACSTAT1), offset 0x040 .....                                | 1185        |
| Register 7: Analog Comparator Control 0 (ACCTL0), offset 0x024 .....                                | 1186        |
| Register 8: Analog Comparator Control 1 (ACCTL1), offset 0x044 .....                                | 1186        |
| Register 9: Analog Comparator Peripheral Properties (ACMPPP), offset 0xFC0 .....                    | 1188        |
| <b>Pulse Width Modulator (PWM) .....</b>                                                            | <b>1189</b> |
| Register 1: PWM Master Control (PWMCTL), offset 0x000 .....                                         | 1203        |
| Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004 .....                                        | 1205        |
| Register 3: PWM Output Enable (PWMENABLE), offset 0x008 .....                                       | 1206        |
| Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C .....                                    | 1208        |
| Register 5: PWM Output Fault (PWMFAULT), offset 0x010 .....                                         | 1210        |
| Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014 .....                                     | 1212        |
| Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018 .....                                   | 1214        |
| Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C .....                             | 1217        |
| Register 9: PWM Status (PWMSTATUS), offset 0x020 .....                                              | 1220        |
| Register 10: PWM Fault Condition Value (PWMFAULTVAL), offset 0x024 .....                            | 1222        |
| Register 11: PWM Enable Update (PWMENUUPD), offset 0x028 .....                                      | 1224        |
| Register 12: PWM0 Control (PWM0CTL), offset 0x040 .....                                             | 1228        |
| Register 13: PWM1 Control (PWM1CTL), offset 0x080 .....                                             | 1228        |
| Register 14: PWM2 Control (PWM2CTL), offset 0x0C0 .....                                             | 1228        |
| Register 15: PWM3 Control (PWM3CTL), offset 0x100 .....                                             | 1228        |
| Register 16: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044 .....                      | 1233        |
| Register 17: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084 .....                      | 1233        |
| Register 18: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4 .....                      | 1233        |
| Register 19: PWM3 Interrupt and Trigger Enable (PWM3INTEN), offset 0x104 .....                      | 1233        |
| Register 20: PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048 .....                                | 1236        |
| Register 21: PWM1 Raw Interrupt Status (PWM1RIS), offset 0x088 .....                                | 1236        |

|              |                                                                    |      |
|--------------|--------------------------------------------------------------------|------|
| Register 22: | PWM2 Raw Interrupt Status (PWM2RIS), offset 0x0C8 .....            | 1236 |
| Register 23: | PWM3 Raw Interrupt Status (PWM3RIS), offset 0x108 .....            | 1236 |
| Register 24: | PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C .....      | 1238 |
| Register 25: | PWM1 Interrupt Status and Clear (PWM1ISC), offset 0x08C .....      | 1238 |
| Register 26: | PWM2 Interrupt Status and Clear (PWM2ISC), offset 0x0CC .....      | 1238 |
| Register 27: | PWM3 Interrupt Status and Clear (PWM3ISC), offset 0x10C .....      | 1238 |
| Register 28: | PWM0 Load (PWM0LOAD), offset 0x050 .....                           | 1240 |
| Register 29: | PWM1 Load (PWM1LOAD), offset 0x090 .....                           | 1240 |
| Register 30: | PWM2 Load (PWM2LOAD), offset 0x0D0 .....                           | 1240 |
| Register 31: | PWM3 Load (PWM3LOAD), offset 0x110 .....                           | 1240 |
| Register 32: | PWM0 Counter (PWM0COUNT), offset 0x054 .....                       | 1241 |
| Register 33: | PWM1 Counter (PWM1COUNT), offset 0x094 .....                       | 1241 |
| Register 34: | PWM2 Counter (PWM2COUNT), offset 0x0D4 .....                       | 1241 |
| Register 35: | PWM3 Counter (PWM3COUNT), offset 0x114 .....                       | 1241 |
| Register 36: | PWM0 Compare A (PWM0CMPA), offset 0x058 .....                      | 1242 |
| Register 37: | PWM1 Compare A (PWM1CMPA), offset 0x098 .....                      | 1242 |
| Register 38: | PWM2 Compare A (PWM2CMPA), offset 0x0D8 .....                      | 1242 |
| Register 39: | PWM3 Compare A (PWM3CMPA), offset 0x118 .....                      | 1242 |
| Register 40: | PWM0 Compare B (PWM0CMPB), offset 0x05C .....                      | 1243 |
| Register 41: | PWM1 Compare B (PWM1CMPB), offset 0x09C .....                      | 1243 |
| Register 42: | PWM2 Compare B (PWM2CMPB), offset 0x0DC .....                      | 1243 |
| Register 43: | PWM3 Compare B (PWM3CMPB), offset 0x11C .....                      | 1243 |
| Register 44: | PWM0 Generator A Control (PWM0GENA), offset 0x060 .....            | 1244 |
| Register 45: | PWM1 Generator A Control (PWM1GENA), offset 0x0A0 .....            | 1244 |
| Register 46: | PWM2 Generator A Control (PWM2GENA), offset 0x0E0 .....            | 1244 |
| Register 47: | PWM3 Generator A Control (PWM3GENA), offset 0x120 .....            | 1244 |
| Register 48: | PWM0 Generator B Control (PWM0GENB), offset 0x064 .....            | 1247 |
| Register 49: | PWM1 Generator B Control (PWM1GENB), offset 0x0A4 .....            | 1247 |
| Register 50: | PWM2 Generator B Control (PWM2GENB), offset 0x0E4 .....            | 1247 |
| Register 51: | PWM3 Generator B Control (PWM3GENB), offset 0x124 .....            | 1247 |
| Register 52: | PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068 .....             | 1250 |
| Register 53: | PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8 .....             | 1250 |
| Register 54: | PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8 .....             | 1250 |

| April 2012 | 12457.2480 | <ul style="list-style-type: none"> <li>■ Document revision number is now auto-generated and indicates the revision of the source files.</li> <li>■ In the JTAG chapter, clarified that the "Recovering a Locked Microcontroller" procedure erases EEPROM and returns its wear-leveling counters to factory default values.</li> <li>■ In the System Control chapter, reorganized registers to group legacy registers at the end of the chapter.</li> <li>■ In the uDMA chapter, in the "uDMA Channel Assignments" and "Request Type Support" tables, corrected to show uDMA support for burst requests from the general-purpose timer, not single requests.</li> <li>■ In the SSI chapter, added the SLBY6 bit to the <b>SSI Control 1 (SSICR1)</b> register. This allows the system clock to operate at least 6 times faster (overriding 12 times faster normally) than SSICLK.</li> <li>■ In the I<sup>2</sup>C chapter, clarified description of Quick Command.</li> <li>■ In the Operating Characteristics chapter, deleted the Maximum power dissipation parameter from the "Thermal Characteristics" table.</li> <li>■ In the Electrical Characteristics chapter:               <ul style="list-style-type: none"> <li>– Removed pending characterization notes in a number of tables where data has been reviewed.</li> <li>– In the Power Characteristics table, adjusted the minimum, nominal, and maximum values for POR and BOR thresholds.</li> <li>– In the Main Oscillator Input Characteristics table, adjusted the maximum value for the main oscillator startup time.</li> <li>– Added Crystal Parameters table.</li> <li>– In the Flash Memory Characteristics table, adjusted the maximum values for T<sub>PROG64</sub> and T<sub>ERASE</sub>.</li> <li>– In the GPIO Module Characteristics table, adjusted the values for the GPIO rise and fall times.</li> <li>– In the ADC Electrical Characteristics table, updated Max value for the ADC input common mode voltage parameter, and adjusted system performance parameter values.</li> <li>– In the SSI Characteristics table, adjusted values for SSIClk rise and fall times.</li> <li>– In Preliminary Current Consumption table, updated Nom value for Deep-sleep mode parameter.</li> </ul> </li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul> |
| March 2012 | 12013      | <ul style="list-style-type: none"> <li>■ In Cortex-M4 Peripherals chapter:               <ul style="list-style-type: none"> <li>– Corrected missing bits in <b>Interrupt 128-138 Set Enable (EN4)</b>, <b>Interrupt 128-138 Clear Enable (DIS4)</b>, <b>Interrupt 128-138 Set Pending (PEND4)</b>, <b>Interrupt 128-138 Clear Pending (UNPEND4)</b>, and <b>Interrupt 128-138 Active Bit (ACTIVE4)</b> registers.</li> <li>– Added missing <b>Interrupt 132-135 Priority (PRI33)</b> and <b>Interrupt 136-138 Priority (PRI34)</b> registers.</li> </ul> </li> <li>■ In the System Control chapter,</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 1. Revision History (*continued*)

| Date | Revision | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## About This Document

This data sheet provides reference information for the LM4F231H5QR microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M4F core.

### Audience

This manual is intended for system software developers, hardware designers, and application developers.

### About This Manual

This document is organized into sections that correspond to each major feature.

## Documentation Conventions

This document uses the conventions shown in Table 2 on page 43.

**Table 2. Documentation Conventions**

| Notation                              | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>General Register Notation</b>      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>REGISTER</b>                       | APB registers are indicated in uppercase bold. For example, <b>PBORCTL</b> is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, <b>SRCRn</b> represents any (or all) of the three Software Reset Control registers: <b>SRCR0</b> , <b>SRCR1</b> , and <b>SRCR2</b> .                                                                                            |
| bit                                   | A single bit in a register.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| bit field                             | Two or more consecutive and related bits.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| offset 0xnnn                          | A hexadecimal increment to a register's address, relative to that module's base address as specified in Table 2-4 on page 93.                                                                                                                                                                                                                                                                                                                                  |
| Register N                            | Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.                                                                                                                                                                                                                                                                                                                       |
| reserved                              | Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                              |
| yy:xx                                 | The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.                                                                                                                                                                                                                                                                                                                                              |
| <b>Register Bit/Field Types</b>       | This value in the register bit diagram indicates whether software running on the controller can change the value of the bit field.                                                                                                                                                                                                                                                                                                                             |
| RC                                    | Software can read this field. The bit or field is cleared by hardware after reading the bit/field.                                                                                                                                                                                                                                                                                                                                                             |
| RO                                    | Software can read this field. Always write the chip reset value.                                                                                                                                                                                                                                                                                                                                                                                               |
| R/W                                   | Software can read or write this field.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| R/WC                                  | Software can read or write this field. Writing to it with any value clears the register.                                                                                                                                                                                                                                                                                                                                                                       |
| R/W1C                                 | Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read. |
| R/W1S                                 | Software can read or write a 1 to this field. A write of a 0 to a R/W1S bit does not affect the bit value in the register.                                                                                                                                                                                                                                                                                                                                     |
| W1C                                   | Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data. This register is typically used to clear the corresponding bit in an interrupt register.                                                                                                         |
| WO                                    | Only a write by software is valid; a read of the register returns no meaningful data.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Register Bit/Field Reset Value</b> | This value in the register bit diagram shows the bit/field value after any reset, unless noted.                                                                                                                                                                                                                                                                                                                                                                |
| 0                                     | Bit cleared to 0 on chip reset.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1                                     | Bit set to 1 on chip reset.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -                                     | Nondeterministic.                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| [ ]                                   | Pin alternate function; a pin defaults to the signal without the brackets.                                                                                                                                                                                                                                                                                                                                                                                     |
| pin                                   | Refers to the physical connection on the package.                                                                                                                                                                                                                                                                                                                                                                                                              |
| signal                                | Refers to the electrical signal encoding of a pin.                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 2. Documentation Conventions (*continued*)**

| Notation                   | Meaning                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assert a signal            | Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see SIGNAL and $\overline{\text{SIGNAL}}$ below). |
| deassert a signal          | Change the value of the signal from the logically True state to the logically False state.                                                                                                                                                                                                                                                  |
| $\overline{\text{SIGNAL}}$ | Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert $\overline{\text{SIGNAL}}$ is to drive it Low; to deassert $\overline{\text{SIGNAL}}$ is to drive it High.                                                                                                    |
| SIGNAL                     | Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert SIGNAL is to drive it High; to deassert SIGNAL is to drive it Low.                                                                                                                                                                   |
| <b>Numbers</b>             |                                                                                                                                                                                                                                                                                                                                             |
| X                          | An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.                                                                                                                                   |
| 0x                         | Hexadecimal numbers have a prefix of 0x. For example, 0x00FF is the hexadecimal number FF. All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.                  |

# 1 Architectural Overview

Texas Instruments is the industry leader in bringing 32-bit capabilities and the full benefits of ARM® Cortex™-M-based microcontrollers to the broadest reach of the microcontroller market. For current users of 8- and 16-bit MCUs, Stellaris® with Cortex-M offers a direct path to the strongest ecosystem of development tools, software and knowledge in the industry. Designers who migrate to Stellaris benefit from great tools, small code footprint and outstanding performance. Even more important, designers can enter the ARM ecosystem with full confidence in a compatible roadmap from \$1 to 1 GHz. With blazingly-fast responsiveness, Thumb-2 technology combines both 16-bit and 32-bit instructions to deliver the best balance of code density and performance. Thumb-2 uses 26 percent less memory than pure 32-bit code to reduce system cost while delivering 25 percent better performance. The Texas Instruments Stellaris family of microcontrollers brings high-performance 32-bit computing to cost-sensitive embedded microcontroller applications.

This chapter contains an overview of the Stellaris LM4F series of microcontrollers as well as details on the LM4F231H5QR microcontroller:

- “Stellaris LM4F Series Overview” on page 45
- “LM4F231H5QR Microcontroller Overview” on page 48
- “LM4F231H5QR Microcontroller Features” on page 51
- “LM4F231H5QR Microcontroller Hardware Details” on page 69

## 1.1 Stellaris LM4F Series Overview

The Stellaris LM4F series of ARM Cortex-M4 microcontrollers provides top performance and advanced integration. The product family is positioned for cost-conscious applications requiring significant control processing and connectivity capabilities such as:

- Low power, hand-held smart devices
- Gaming equipment
- Home and commercial site monitoring and control
- Motion control
- Medical instrumentation
- Test and measurement equipment
- Factory automation
- Fire and security
- Smart Energy/Smart Grid solutions
- Intelligent lighting control
- Transportation

Figure 1-1. Stellaris LM4F Block Diagram

The Stellaris LM4F microcontrollers consist of fifteen pin-compatible series of devices, summarized below. Each series has a range of embedded Flash and SRAM sizes.

Table 1-1. Stellaris LM4F Device Series

| General MCU (LM4F11x Series) | General MCU + USB Device (LM4F12x Series) | General MCU + USB OTG (LM4F13x Series) | Motion Control (LM4F21x Series) | Motion Control + USB OTG (LM4F23x Series) | Package                                                                 |
|------------------------------|-------------------------------------------|----------------------------------------|---------------------------------|-------------------------------------------|-------------------------------------------------------------------------|
| LM4F110                      | LM4F120                                   | LM4F130                                | LM4F210                         | LM4F230                                   | 64-pin LQFP                                                             |
| LM4F111                      | LM4F121                                   | LM4F131                                | LM4F211                         | LM4F231                                   | 64-pin LQFP                                                             |
| LM4F112                      | LM4F122                                   | LM4F132                                | LM4F212                         | LM4F232                                   | 100-pin LQFP<br>144-pin LQFP<br>157-ball BGA (LM4F212 and LM4F232 only) |

The Stellaris LM4F23x Series for MCU control applications with advanced motion control timers and USB OTG/ Host/Device offers advanced motion control timers and USB OTG/Host/Device capability with a generous number of serial peripherals in four packages.

Table 1-2. Stellaris LM4F23x Series

| Part Number | Flash (KB) | SRAM (KB) | 5-V Tolerant GPIOs | Package      | Notes                                                                                                                                     |
|-------------|------------|-----------|--------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| LM4F230E5QR | 128        | 32        | 43                 | 64-pin LQFP  | Includes low-power hibernate functionality.                                                                                               |
| LM4F230H5QR | 256        | 32        |                    |              |                                                                                                                                           |
| LM4F231E5QR | 128        | 32        | 49                 | 64-pin LQFP  | No low-power hibernate functionality, but includes additional serial functionality, and up to six more I/Os than the LM4F230 Series.      |
| LM4F231H5QR | 256        | 32        |                    |              |                                                                                                                                           |
| LM4F232E5QC | 128        | 32        | 69                 | 100-pin LQFP | Includes low-power hibernate functionality, and additional motion control, serial, and analog functionality in larger pin-count packages. |
| LM4F232H5QC | 256        | 32        |                    |              |                                                                                                                                           |
| LM4F232H5QD | 256        | 32        | 105                | 144-pin LQFP |                                                                                                                                           |
| LM4F232H5BB | 256        | 32        |                    |              |                                                                                                                                           |
|             |            |           | 120                | 157-ball BGA |                                                                                                                                           |

a. USB options for Stellaris microcontrollers include Device Only (D) capability, Host/Device (H) capability, and On-The-Go/Host/Device capability (O).

b. Minimum is number of pins dedicated to GPIO; additional pins are available if certain peripherals are not used. See data sheet for details.

## 1.2 LM4F231H5QR Microcontroller Overview

The Stellaris LM4F231H5QR microcontroller combines complex integration and high performance with the features shown in Table 1-4.

Table 1-4. Stellaris LM4F231H5QR Microcontroller Features

| Feature     | Description                             |
|-------------|-----------------------------------------|
| Core        | ARM Cortex-M4F processor core           |
| Performance | 80-MHz operation; 100 DMIPS performance |
| Flash       | 256 KB single-cycle Flash memory        |

**Table 1-4. Stellaris LM4F231H5QR Microcontroller Features (continued)**

| Feature                                             | Description                                                                          |
|-----------------------------------------------------|--------------------------------------------------------------------------------------|
| System SRAM                                         | 32 KB single-cycle SRAM                                                              |
| EEPROM                                              | 2KB of EEPROM                                                                        |
| Internal ROM                                        | Internal ROM loaded with StellarisWare® software                                     |
| <b>Communication Interfaces</b>                     |                                                                                      |
| Universal Asynchronous Receivers/Transmitter (UART) | Eight UARTs                                                                          |
| Synchronous Serial Interface (SSI)                  | Four SSI modules                                                                     |
| Inter-Integrated Circuit (I <sup>2</sup> C)         | Six I <sup>2</sup> C modules with four transmission speeds including high-speed mode |
| Controller Area Network (CAN)                       | Two CAN 2.0 A/B controllers                                                          |
| Universal Serial Bus (USB)                          | USB 2.0 OTG/Host/Device                                                              |
| <b>System Integration</b>                           |                                                                                      |
| Micro Direct Memory Access (μDMA)                   | ARM® PrimeCell® 32-channel configurable μDMA controller                              |
| General-Purpose Timer (GPTM)                        | Six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks                         |
| Watchdog Timer (WDT)                                | Two watchdog timers                                                                  |
| General-Purpose Input/Output (GPIO)                 | Seven physical GPIO blocks                                                           |
| <b>Advanced Motion Control</b>                      |                                                                                      |
| Pulse Width Modulator (PWM)                         | Two PWM modules                                                                      |
| Quadrature Encoder Interface (QEI)                  | Two QEI modules                                                                      |
| <b>Analog Support</b>                               |                                                                                      |
| Analog-to-Digital Converter (ADC)                   | Two 12-bit ADC modules                                                               |
| Analog Comparator Controller                        | Two independent integrated analog comparators                                        |
| Digital Comparator                                  | 16 digital comparators                                                               |
| JTAG and Serial Wire Debug (SWD)                    | One JTAG module with integrated ARM SWD                                              |
| Package                                             | 64-pin LQFP                                                                          |
| Operating Range                                     | Industrial (-40°C to 85°C) temperature range                                         |

Figure 1-2 on page 50 shows the features on the Stellaris LM4F231H5QR microcontroller. Note that there are two on-chip buses that connect the core to the peripherals. The Advanced Peripheral Bus (APB) bus is the legacy bus. The Advanced High-Performance Bus (AHB) bus provides better back-to-back access performance than the APB bus.

Figure 1-2. Stellaris LM4F231H5QR Microcontroller High-Level Block Diagram

In addition, the LM4F231H5QR microcontroller offers the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure IP applications, and a large user community. Additionally, the microcontroller uses ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the LM4F231H5QR microcontroller is code-compatible to all members of the extensive Stellaris family; providing flexibility to fit precise needs.

Texas Instruments offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network.

## **1.3 LM4F231H5QR Microcontroller Features**

The LM4F231H5QR microcontroller component features and general function are discussed in more detail in the following section.

### **1.3.1 ARM Cortex-M4F Processor Core**

All members of the Stellaris product family, including the LM4F231H5QR microcontroller, are designed around an ARM Cortex-M processor core. The ARM Cortex-M processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

#### **1.3.1.1 Processor Core (see page 70)**

- 32-bit ARM Cortex-M4F architecture optimized for small-footprint embedded applications
- 80-MHz operation; 100 DMIPS performance
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing

- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7 processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage
- Ultra-low power consumption with integrated sleep modes

#### **1.3.1.2 System Timer (SysTick) (see page 124)**

ARM Cortex-M4F includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit, clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter
- A simple counter used to measure time to completion and time used
- An internal clock-source control based on missing/meeting durations.

#### **1.3.1.3 Nested Vectored Interrupt Controller (NVIC) (see page 125)**

The LM4F231H5QR controller includes the ARM Nested Vectored Interrupt Controller (NVIC). The NVIC and Cortex-M4F prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The interrupt vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, meaning that back-to-back interrupts can be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 80 interrupts.

- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications
- Dynamically reprioritizable interrupts
- Exceptional interrupt handling via hardware implementation of required register manipulations

#### **1.3.1.4 System Control Block (SCB) (see page 126)**

The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

### 1.3.1.5 Memory Protection Unit (MPU) (see page 126)

The MPU supports the standard ARM7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

### 1.3.1.6 Floating-Point Unit (FPU) (see page 131)

The FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined Multiply and Accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

## 1.3.2 On-Chip Memory

The LM4F231H5QR microcontroller is integrated with the following set of on-chip memory and features:

- 32 KB single-cycle SRAM
- 256 KB single-cycle Flash memory
- Internal ROM loaded with StellarisWare software:
  - Stellaris Peripheral Driver Library
  - Stellaris Boot Loader
  - Advanced Encryption Standard (AES) cryptography tables
  - Cyclic Redundancy Check (CRC) error detection functionality
- 2KB EEPROM

### 1.3.2.1 SRAM (see page 502)

The LM4F231H5QR microcontroller provides 32 KB of single-cycle on-chip SRAM. The internal SRAM of the Stellaris devices is located at offset 0x2000.0000 of the device memory map.

Because read-modify-write (RMW) operations are very time consuming, ARM has introduced *bit-banding* technology in the Cortex-M4F processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

Data can be transferred to and from the SRAM using the Micro Direct Memory Access Controller (μDMA).

### 1.3.2.2 Flash Memory (see page 505)

The LM4F231H5QR microcontroller provides 256 KB of single-cycle on-chip Flash memory. The Flash memory is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. These blocks are paired into a set of 2-KB blocks that can be individually protected. The blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

### 1.3.2.3 ROM (see page 503)

The LM4F231H5QR ROM is preprogrammed with the following software and programs:

- Stellaris Peripheral Driver Library
- Stellaris Boot Loader
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error-detection functionality

The Stellaris Peripheral Driver Library is a royalty-free software library for controlling on-chip peripherals with a boot-loader capability. The library performs both peripheral initialization and control functions, with a choice of polled or interrupt-driven peripheral support. In addition, the library is designed to take full advantage of the stellar interrupt performance of the ARM Cortex-M4F core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free Stellaris Boot Loader can act as an application loader and support in-field firmware updates.

The Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. AES is a strong encryption method with reasonable performance and size. In addition, it is fast in both hardware and software, is fairly easy to implement, and requires little memory. The Texas Instruments encryption package is available with full source code, and is based on lesser general public license (LGPL) source. An LGPL means that the code can be used within an application without any copyleft implications for the application (the code does not automatically become open source). Modifications to the package source, however, must be open source.

CRC (Cyclic Redundancy Check) is a technique to validate a span of data has the same contents as when previously checked. This technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily.

### 1.3.2.4 EEPROM (see page 509)

The LM4F231H5QR microcontroller includes an EEPROM with the following features:

- 2K bytes of memory accessible as 512 32-bit words
- 32 blocks of 16 words (64 bytes) each
- Built-in wear leveling

- Access protection per block
- Lock protection option for the whole peripheral as well as per block using 32-bit to 96-bit unlock codes (application selectable)
- Interrupt support for write completion to avoid polling
- Endurance of 500K writes (when writing at fixed offset in every alternate page in circular fashion) to 15M operations (when cycling through two pages ) per each 2-page block.

### 1.3.3 Serial Communications Peripherals

The LM4F231H5QR controller supports both asynchronous and synchronous serial communications with:

- Two CAN 2.0 A/B controllers
- USB 2.0 OTG/Host/Device
- Eight UARTs with IrDA, 9-bit and ISO 7816 support (one UART with modem flow control)
- Six I<sup>2</sup>C modules with four transmission speeds including high-speed mode
- Four Synchronous Serial Interface modules (SSI)

The following sections provide more detail on each of these communications functions.

#### 1.3.3.1 Controller Area Network (see page 1008)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or twisted-pair wire. Originally created for automotive purposes, it is now used in many embedded control applications (for example, industrial or medical). Bit rates up to 1 Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit from 0 to 8 bytes of user information.

The LM4F231H5QR microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects

- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

### 1.3.3.2 USB (see page 1059)

Universal Serial Bus (USB) is a serial bus standard designed to allow peripherals to be connected and disconnected using a standardized interface without rebooting the system.

The LM4F231H5QR microcontroller supports three configurations in USB 2.0 full and low speed: USB Device, USB Host, and USB On-The-Go (negotiated on-the-go as host or device when connected to other USB-enabled systems).

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation with integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop and valid ID detection and interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive for up to three IN endpoints and three OUT endpoints
  - Channel requests asserted when FIFO contains required amount of data

### 1.3.3.3 UART (see page 855)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The LM4F231H5QR microcontroller includes eight fully programmable 16C550-type UARTs. Although the functionality is similar to a 16C550 UART, this UART design is not register compatible. The UART can generate individually masked interrupts from the Rx, Tx, modem flow control, and error conditions. The module generates a single combined interrupt when any of the interrupts are asserted and are unmasked.

The eight UARTs have the following features:

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface

- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem flow control (on UART1)
- LIN protocol support
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

#### 1.3.3.4 I<sup>2</sup>C (see page 961)

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL). The I<sup>2</sup>C bus interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

Each device on the I<sup>2</sup>C bus can be designated as either a master or a slave. I<sup>2</sup>C module supports both sending and receiving data as either a master or a slave and can operate simultaneously as both a master and a slave. Both the I<sup>2</sup>C master and slave can generate interrupts.

The LM4F231H5QR microcontroller includes six I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Four transmission speeds:
  - Standard (100 Kbps)
  - Fast-mode (400 Kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Clock low timeout interrupt
- Dual slave address capability
- Clock low timeout interrupt
- Dual slave address capability
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

#### **1.3.3.5 SSI (see page 918)**

Synchronous Serial Interface (SSI) is a four-wire bi-directional communications interface that converts data between parallel and serial. The SSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The SSI module can be configured as either a master or slave device. As a slave device, the SSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices. The TX and RX paths are buffered with separate internal FIFOs.

The SSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the SSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

The LM4F231H5QR microcontroller includes four SSI modules with the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when FIFO contains 4 entries

### 1.3.4 System Integration

The LM4F231H5QR microcontroller provides a variety of standard system functions integrated into the device, including:

- Direct Memory Access Controller (DMA)
- System control and clocks including on-chip precision 16-MHz oscillator
- Six 32-bit timers (up to twelve 16-bit), with real-time clock capability
- Six wide 64-bit timers (up to twelve 32-bit), with real-time clock capability
- Twelve 16/32-bit Capture Compare PWM (CCP) pins
- Twelve 32/64-bit Capture Compare PWM (CCP) pins
- Two Watchdog Timers
  - One timer runs off the main oscillator
  - One timer runs off the precision internal oscillator
- Up to 49 GPIOs, depending on configuration
  - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
  - Independently configurable to 2, 4 or 8 mA drive capability
  - Up to 4 GPIOs can have 18 mA drive capability

The following sections provide more detail on each of these functions.

#### **1.3.4.1 Direct Memory Access (see page 559)**

The LM4F231H5QR microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA ( $\mu$ DMA). The  $\mu$ DMA controller provides a way to offload data transfer tasks from the Cortex-M4F processor, allowing for more efficient use of the processor and the available bus bandwidth. The  $\mu$ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The  $\mu$ DMA controller provides the following features:

- ARM PrimeCell<sup>®</sup> 32-channel configurable  $\mu$ DMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
  - Basic for simple transfer scenarios
  - Ping-pong for continuous data flow
  - Scatter-gather for a programmable list of arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules
  - Flexible channel assignments
  - One channel each for receive and transmit path for bidirectional modules
  - Dedicated channel for software-initiated transfers
  - Per-channel configurable priority scheme
  - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between  $\mu$ DMA controller and the processor core
  - $\mu$ DMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment

- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

#### 1.3.4.2 System Control and Clocks (see page 213)

System control determines the overall operation of the device. It provides information about the device, controls power-saving features, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

- Device identification information: version, part number, SRAM size, Flash memory size, and so on
- Power control
  - On-chip fixed Low Drop-Out (LDO) voltage regulator
  - Low-power options for microcontroller: Sleep and Deep-sleep modes with clock gating
  - Low-power options for on-chip modules: software controls shutdown of individual peripherals and memory
  - 3.3-V supply brown-out detection and reporting via interrupt or reset
- Multiple clock sources for microcontroller system clock
  - Precision Oscillator (PIOSC): On-chip resource providing a 16 MHz  $\pm 1\%$  frequency at room temperature
    - 16 MHz  $\pm 3\%$  across temperature
    - Software power down control for low power modes
  - Main Oscillator (MOSC): A frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins.
    - External crystal used with or without on-chip PLL: select supported frequencies from 4 MHz to 25 MHz.
    - External oscillator: from DC to maximum device speed
  - Internal 30-kHz Oscillator: on chip resource providing a 30 kHz  $\pm 50\%$  frequency, used during power-saving modes
- Flexible reset sources
  - Power-on reset (POR)
  - Reset pin assertion
  - Brown-out reset (BOR) detector alerts to system power drops
  - Software reset
  - Watchdog timer reset
  - MOSC failure

### 1.3.4.3 Programmable Timers (see page 677)

Programmable timers can be used to count or time external events that drive the Timer input pins. Each 16/32-bit GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Each 32/64-bit Wide GPTM block provides two 32-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 64-bit timer or one 64-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions.

The General-Purpose Timer Module (GPTM) contains six 16/32-bit GPTM blocks and six 32/64-bit Wide GPTM blocks with the following functional options:

- 16/32-bit operating modes:
  - 16- or 32-bit programmable one-shot timer
  - 16- or 32-bit programmable periodic timer
  - 16-bit general-purpose timer with an 8-bit prescaler
  - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
  - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
  - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
- 32/64-bit operating modes:
  - 32- or 64-bit programmable one-shot timer
  - 32- or 64-bit programmable periodic timer
  - 32-bit general-purpose timer with a 16-bit prescaler
  - 64-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
  - 32-bit input-edge count- or time-capture modes with a 16-bit prescaler
  - 32-bit PWM mode with a 16-bit prescaler and software-programmable output inversion of the PWM signal
- Count up or down
- Twelve 16/32-bit Capture Compare PWM pins (CCP)
- Twelve 32/64-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)

- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine.
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

#### 1.3.4.4 CCP Pins (see page 685)

Capture Compare PWM pins (CCP) can be used by the General-Purpose Timer Module to time/count external events using the CCP pin as an input. Alternatively, the GPTM can generate a simple PWM output on the CCP pin.

The LM4F231H5QR microcontroller includes twelve 16/32-bit CCP pins that can be programmed to operate in the following modes:

- Capture: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer captures and stores the current timer value when a programmed event occurs.
- Compare: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer compares the current value with a stored value and generates an interrupt when a match occurs.
- PWM: The GP Timer is incremented/decremented by the system clock. A PWM signal is generated based on a match between the counter value and a value stored in a match register and is output on the CCP pin.

#### 1.3.4.5 Watchdog Timers (see page 747)

A watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way. The Stellaris Watchdog Timer can generate an interrupt, a non-maskable interrupt, or a reset when a time-out value is reached. In addition, the Watchdog Timer is ARM FiRM-compliant and can be configured to generate an interrupt to the microcontroller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

The LM4F231H5QR microcontroller has two Watchdog Timer modules: Watchdog Timer 0 uses the system clock for its timer clock; Watchdog Timer 1 uses the PIOSC as its timer clock. The Stellaris Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

#### 1.3.4.6 Programmable GPIOs (see page 623)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections. The Stellaris GPIO module is comprised of seven physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FIRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 0-49 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 1291 for the signals available to each GPIO pin).

- Up to 49 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant in input configuration
- Two means of port access: either Advanced High-Performance Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code for Ports A-G
- Fast toggle capable of a change every clock cycle for ports on AHB, every two clock cycles for ports on APB
- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence or a  $\mu$ DMA transfer
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can sink 18-mA for high-current applications
  - Slew rate control for 8-mA pad drive
  - Open drain enables
  - Digital input enables

#### 1.3.5 Advanced Motion Control

The LM4F231H5QR microcontroller provides motion control functions integrated into the device, including:

- Two PWM modules, with a total of 16 advanced PWM outputs for motion and energy applications
- Six fault inputs to promote low-latency shutdown

- Two Quadrature Encoder Inputs (QEI)

The following provides more detail on these motion control functions.

### 1.3.5.1 PWM (see page 1189)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control. Each LM4F231H5QR PWM module consists of four PWM generator block and a control block. Each PWM generator block contains one timer (16-bit down or up/down counter), two comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. Each PWM generator block produces two PWM signals that can either be independent signals or a single pair of complementary signals with dead-band delays inserted.

Each PWM generator has the following features:

- Three fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled, for a total of six inputs
- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified
- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal

- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Extended PWM synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

#### 1.3.5.2 QEI (see page 1268)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, the position, direction of rotation, and speed can be tracked. In addition, a third channel, or index signal, can be used to reset the position counter. The Stellaris quadrature encoder with index (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel. The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 20 MHz for a 80-MHz system).

The LM4F231H5QR microcontroller includes two QEI modules providing control of two motors at the same time with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

#### 1.3.6 Analog

The LM4F231H5QR microcontroller provides analog functions integrated into the device, including:

- Two 12-bit Analog-to-Digital Converters (ADC) with 12 analog input channels and a sample rate of one million samples/second
- Two analog comparators

- 16 digital comparators
- On-chip voltage regulator

The following provides more detail on these analog functions.

### 1.3.6.1 ADC (see page 772)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. The Stellaris ADC module features 12-bit conversion resolution and supports 12 input channels plus an internal temperature sensor. Four buffered sample sequencers allow rapid sampling of up to 12 analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. Each ADC module has a digital comparator function that allows the conversion value to be diverted to a comparison unit that provides eight digital comparators.

The LM4F231H5QR microcontroller provides two ADC modules with the following features:

- 12 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional phase shift in sample time programmable from 22.5° to 337.5°
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples
- Digital comparison unit providing eight digital comparators
- Converter uses VDDA and GNDA as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each sample sequencer

- ADC module uses burst requests for DMA

### 1.3.6.2 Analog Comparators (see page 1174)

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result. The LM4F231H5QR microcontroller provides two independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The LM4F231H5QR microcontroller provides two independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

### 1.3.7 JTAG and ARM Serial Wire Debug (see page 201)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging. Texas Instruments replaces the ARM SW-DP and JTAG-DP with the ARM Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module providing all the normal JTAG debug and test functionality plus real-time access to system memory without halting the core or requiring any target resident code. The SWJ-DP interface has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints

- Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
- Instrumentation Trace Macrocell (ITM) for support of printf style debugging
- Embedded Trace Macrocell (ETM) for instruction trace capture
- Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

### **1.3.8 Packaging and Temperature**

- Industrial-range (-40°C to 85°C) 64-pin RoHS-compliant LQFP package

## **1.4 LM4F231H5QR Microcontroller Hardware Details**

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 1290
- “Signal Tables” on page 1291
- “Operating Characteristics” on page 1321
- “Electrical Characteristics” on page 1322
- “Package Information” on page 1399

## 2 The Cortex-M4F Processor

The ARM® Cortex™-M4F processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- 32-bit ARM® Cortex™-M4F architecture optimized for small-footprint embedded applications
- 80-MHz operation; 100 DMIPS performance
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7 processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage
- Ultra-low power consumption with integrated sleep modes

The Stellaris® family of microcontrollers builds on this core to bring high-performance 32-bit computing to cost-sensitive embedded microcontroller applications, such as factory automation and control, industrial control power devices, building and home automation, and stepper motor control.

This chapter provides information on the Stellaris implementation of the Cortex-M4F processor, including the programming model, the memory model, the exception model, fault handling, and power management.

For technical details on the instruction set, see the *ARM® Cortex™-M4 Technical Reference Manual*.

## 2.1 Block Diagram

The Cortex-M4F processor is built on a high-performance processor core, with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and extensively optimized design, providing high-end processing hardware including IEEE754-compliant single-precision floating-point computation, a range of single-cycle and SIMD multiplication and multiply-with-accumulate capabilities, saturating arithmetic and dedicated hardware division.

To facilitate the design of cost-sensitive devices, the Cortex-M4F processor implements tightly coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities. The Cortex-M4F processor implements a version of the Thumb® instruction set based on Thumb-2 technology, ensuring high code density and reduced program memory requirements. The Cortex-M4F instruction set provides the exceptional performance expected of a modern 32-bit architecture, with the high code density of 8-bit and 16-bit microcontrollers.

The Cortex-M4F processor closely integrates a nested interrupt controller (NVIC), to deliver industry-leading interrupt performance. The Stellaris NVIC includes a non-maskable interrupt (NMI) and provides eight interrupt priority levels. The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing interrupt latency. The hardware stacking of registers and the ability to suspend load-multiple and store-multiple operations further reduce interrupt latency. Interrupt handlers do not require any assembler stubs which removes code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another. To optimize low-power designs, the NVIC integrates with the sleep modes, including Deep-sleep mode, which enables the entire device to be rapidly powered down.

Figure 2-1. CPU Block Diagram

## 2.2 Overview

### 2.2.1 System-Level Interface

The Cortex-M4F processor provides multiple interfaces using AMBA® technology to provide high-speed, low-latency memory accesses. The core supports unaligned data accesses and implements atomic bit manipulation that enables faster peripheral controls, system spinlocks, and thread-safe Boolean data handling.

The Cortex-M4F processor has a memory protection unit (MPU) that provides fine-grain memory control, enabling applications to implement security privilege levels and separate code, data and stack on a task-by-task basis.

### 2.2.2 Integrated Configurable Debug

The Cortex-M4F processor implements a complete hardware debug solution, providing high system visibility of the processor and memory through either a traditional JTAG port or a 2-pin Serial Wire Debug (SWD) port that is ideal for microcontrollers and other small package devices. The Stellaris implementation replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *ARM® Debug Interface V5 Architecture Specification* for details on SWJ-DP.

For system trace, the processor integrates an Instrumentation Trace Macrocell (ITM) alongside data watchpoints and a profiling unit. To enable simple and cost-effective profiling of the system trace events, a Serial Wire Viewer (SWV) can export a stream of software-generated messages, data trace, and profiling information through a single pin.

The Embedded Trace Macrocell (ETM) delivers unrivaled instruction trace capture in an area smaller than traditional trace units, enabling full instruction trace. For more details on the ARM ETM, see the *ARM® Embedded Trace Macrocell Architecture Specification*.

The Flash Patch and Breakpoint Unit (FPB) provides up to eight hardware breakpoint comparators that debuggers can use. The comparators in the FPB also provide remap functions of up to eight words in the program code in the CODE memory region. This enables applications stored in a read-only area of Flash memory to be patched in another area of on-chip SRAM or Flash memory. If a patch is required, the application programs the FPB to remap a number of addresses. When those addresses are accessed, the accesses are redirected to a remap table specified in the FPB configuration.

For more information on the Cortex-M4F debug capabilities, see the *ARM® Debug Interface V5 Architecture Specification*.

### 2.2.3 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M4F trace data from the ITM, and an off-chip Trace Port Analyzer, as shown in Figure 2-2 on page 73.

**Figure 2-2. TPIU Block Diagram**

### 2.2.4 Cortex-M4F System Component Details

The Cortex-M4F includes the following system components:

- SysTick

A 24-bit count-down timer that can be used as a Real-Time Operating System (RTOS) tick timer or as a simple counter (see “System Timer (SysTick)” on page 124).

- Nested Vectored Interrupt Controller (NVIC)

An embedded interrupt controller that supports low latency interrupt processing (see “Nested Vectored Interrupt Controller (NVIC)” on page 125).

- System Control Block (SCB)

The programming model interface to the processor. The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions (see “System Control Block (SCB)” on page 126).

- Memory Protection Unit (MPU)

Improves system reliability by defining the memory attributes for different memory regions. The MPU provides up to eight different regions and an optional predefined background region (see “Memory Protection Unit (MPU)” on page 126).

- Floating-Point Unit (FPU)

Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square-root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

## 2.3 Programming Model

This section describes the Cortex-M4F programming model. In addition to the individual core register descriptions, information about the processor modes and privilege levels for software execution and stacks is included.

### 2.3.1 Processor Mode and Privilege Levels for Software Execution

The Cortex-M4F has two modes of operation:

- Thread mode

Used to execute application software. The processor enters Thread mode when it comes out of reset.

- Handler mode

Used to handle exceptions. When the processor has finished exception processing, it returns to Thread mode.

In addition, the Cortex-M4F has two privilege levels:

- Unprivileged

In this mode, software has the following restrictions:

- Limited access to the MSR and MRS instructions and no use of the CPS instruction
- No access to the system timer, NVIC, or system control block
- Possibly restricted access to memory or peripherals

- Privileged

In this mode, software can use all the instructions and has access to all resources.

In Thread mode, the **CONTROL** register (see page 89) controls whether software execution is privileged or unprivileged. In Handler mode, software execution is always privileged.

Only privileged software can write to the **CONTROL** register to change the privilege level for software execution in Thread mode. Unprivileged software can use the SVC instruction to make a supervisor call to transfer control to privileged software.

### 2.3.2 Stacks

The processor uses a full descending stack, meaning that the stack pointer indicates the last stacked item on the memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location. The processor implements two stacks: the main stack and the process stack, with a pointer for each held in independent registers (see the **SP** register on page 79).

In Thread mode, the **CONTROL** register (see page 89) controls whether the processor uses the main stack or the process stack. In Handler mode, the processor always uses the main stack. The options for processor operations are shown in Table 2-1 on page 75.

**Table 2-1. Summary of Processor Mode, Privilege Level, and Stack Use**

| Processor Mode | Use                | Privilege Level                         | Stack Used                               |
|----------------|--------------------|-----------------------------------------|------------------------------------------|
| Thread         | Applications       | Privileged or unprivileged <sup>a</sup> | Main stack or process stack <sup>a</sup> |
| Handler        | Exception handlers | Always privileged                       | Main stack                               |

a. See **CONTROL** (page 89).

### 2.3.3 Register Map

Figure 2-3 on page 76 shows the Cortex-M4F register set. Table 2-2 on page 76 lists the Core registers. The core registers are not memory mapped and are accessed by register name, so the base address is n/a (not applicable) and there is no offset.

Figure 2-3. Cortex-M4F Register Set

Table 2-2. Processor Register Map

| Offset | Name | Type | Reset | Description                        | See page |
|--------|------|------|-------|------------------------------------|----------|
| -      | R0   | R/W  | -     | Cortex General-Purpose Register 0  | 78       |
| -      | R1   | R/W  | -     | Cortex General-Purpose Register 1  | 78       |
| -      | R2   | R/W  | -     | Cortex General-Purpose Register 2  | 78       |
| -      | R3   | R/W  | -     | Cortex General-Purpose Register 3  | 78       |
| -      | R4   | R/W  | -     | Cortex General-Purpose Register 4  | 78       |
| -      | R5   | R/W  | -     | Cortex General-Purpose Register 5  | 78       |
| -      | R6   | R/W  | -     | Cortex General-Purpose Register 6  | 78       |
| -      | R7   | R/W  | -     | Cortex General-Purpose Register 7  | 78       |
| -      | R8   | R/W  | -     | Cortex General-Purpose Register 8  | 78       |
| -      | R9   | R/W  | -     | Cortex General-Purpose Register 9  | 78       |
| -      | R10  | R/W  | -     | Cortex General-Purpose Register 10 | 78       |
| -      | R11  | R/W  | -     | Cortex General-Purpose Register 11 | 78       |

Table 2-2. Processor Register Map (*continued*)

| Offset | Name      | Type | Reset       | Description                        | See page |
|--------|-----------|------|-------------|------------------------------------|----------|
| -      | R12       | R/W  | -           | Cortex General-Purpose Register 12 | 78       |
| -      | SP        | R/W  | -           | Stack Pointer                      | 79       |
| -      | LR        | R/W  | 0xFFFF.FFFF | Link Register                      | 80       |
| -      | PC        | R/W  | -           | Program Counter                    | 81       |
| -      | PSR       | R/W  | 0x0100.0000 | Program Status Register            | 82       |
| -      | PRIMASK   | R/W  | 0x0000.0000 | Priority Mask Register             | 86       |
| -      | FAULTMASK | R/W  | 0x0000.0000 | Fault Mask Register                | 87       |
| -      | BASEPRI   | R/W  | 0x0000.0000 | Base Priority Mask Register        | 88       |
| -      | CONTROL   | R/W  | 0x0000.0000 | Control Register                   | 89       |
| -      | FPSC      | R/W  | -           | Floating-Point Status Control      | 91       |

### 2.3.4 Register Descriptions

This section lists and describes the Cortex-M4F registers, in the order shown in Figure 2-3 on page 76. The core registers are not memory mapped and are accessed by register name rather than offset.

**Note:** The register type shown in the register descriptions refers to type during program execution in Thread mode and Handler mode. Debug access can differ.

- Register 1: Cortex General-Purpose Register 0 (R0)
- Register 2: Cortex General-Purpose Register 1 (R1)
- Register 3: Cortex General-Purpose Register 2 (R2)
- Register 4: Cortex General-Purpose Register 3 (R3)
- Register 5: Cortex General-Purpose Register 4 (R4)
- Register 6: Cortex General-Purpose Register 5 (R5)
- Register 7: Cortex General-Purpose Register 6 (R6)
- Register 8: Cortex General-Purpose Register 7 (R7)
- Register 9: Cortex General-Purpose Register 8 (R8)
- Register 10: Cortex General-Purpose Register 9 (R9)
- Register 11: Cortex General-Purpose Register 10 (R10)
- Register 12: Cortex General-Purpose Register 11 (R11)
- Register 13: Cortex General-Purpose Register 12 (R12)

The **Rn** registers are 32-bit general-purpose registers for data operations and can be accessed from either privileged or unprivileged mode.

Cortex General-Purpose Register 0 (R0)

Type R/W, reset -

| Bit/Field | Name | Type | Reset | Description    |
|-----------|------|------|-------|----------------|
| 31:0      | DATA | R/W  | -     | Register data. |

## Register 14: Stack Pointer (SP)

The **Stack Pointer (SP)** is register R13. In Thread mode, the function of this register changes depending on the ASP bit in the **Control Register (CONTROL)** register. When the ASP bit is clear, this register is the **Main Stack Pointer (MSP)**. When the ASP bit is set, this register is the **Process Stack Pointer (PSP)**. On reset, the ASP bit is clear, and the processor loads the **MSP** with the value from address 0x0000.0000. The **MSP** can only be accessed in privileged mode; the **PSP** can be accessed in either privileged or unprivileged mode.

### Stack Pointer (SP)

Type R/W, reset -

|       |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|       | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|       | SP  |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Type  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   |
|       | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|       | SP  |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Type  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   |

| Bit/Field | Name | Type | Reset | Description                                     |
|-----------|------|------|-------|-------------------------------------------------|
| 31:0      | SP   | R/W  | -     | This field is the address of the stack pointer. |

Register 15: Link Register (LR)

The **Link Register (LR)** is register R14, and it stores the return information for subroutines, function calls, and exceptions. **LR** can be accessed from either privileged or unprivileged mode.

EXC\_RETURN is loaded into **LR** on exception entry. See Table 2-10 on page 112 for the values and description.

Link Register (LR)

Type R/W, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset       | Description                       |
|-----------|------|------|-------------|-----------------------------------|
| 31:0      | LINK | R/W  | 0xFFFF.FFFF | This field is the return address. |

## Register 16: Program Counter (PC)

The **Program Counter (PC)** is register R15, and it contains the current program address. On reset, the processor loads the **PC** with the value of the reset vector, which is at address 0x0000.0004. Bit 0 of the reset vector is loaded into the **THUMB** bit of the **EPSR** at reset and must be 1. The **PC** register can be accessed in either privileged or unprivileged mode.

### Program Counter (PC)

Type R/W, reset -

|       |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|       | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|       | PC  |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Type  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   |
|       | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|       | PC  |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Type  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   | -   |

| Bit/Field | Name | Type | Reset | Description                                |
|-----------|------|------|-------|--------------------------------------------|
| 31:0      | PC   | R/W  | -     | This field is the current program address. |

**Register 17: Program Status Register (PSR)**

**Note:** This register is also referred to as **xPSR**.

The **Program Status Register (PSR)** has three functions, and the register bits are assigned to the different functions:

- **Application Program Status Register (APSR)**, bits 31:27, bits 19:16
- **Execution Program Status Register (EPSR)**, bits 26:24, 15:10
- **Interrupt Program Status Register (IPSR)**, bits 7:0

The **PSR**, **IPSR**, and **EPSR** registers can only be accessed in privileged mode; the **APSR** register can be accessed in either privileged or unprivileged mode.

**APSR** contains the current state of the condition flags from previous instruction executions.

**EPSR** contains the Thumb state bit and the execution state bits for the If-Then (IT) instruction or the Interruptible-Continuable Instruction (ICI) field for an interrupted load multiple or store multiple instruction. Attempts to read the **EPSR** directly through application software using the MSR instruction always return zero. Attempts to write the **EPSR** using the MSR instruction in application software are always ignored. Fault handlers can examine the **EPSR** value in the stacked **PSR** to determine the operation that faulted (see “Exception Entry and Return” on page 109).

**IPSR** contains the exception type number of the current Interrupt Service Routine (ISR).

These registers can be accessed individually or as a combination of any two or all three registers, using the register name as an argument to the MSR or MRS instructions. For example, all of the registers can be read using **PSR** with the MRS instruction, or **APSR** only can be written to using **APSR** with the MSR instruction. page 82 shows the possible register combinations for the **PSR**. See the MRS and MSR instruction descriptions in the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information about how to access the program status registers.

**Table 2-3. PSR Register Combinations**

| Register     | Type                | Combination                                 |
|--------------|---------------------|---------------------------------------------|
| <b>PSR</b>   | R/W <sup>a, b</sup> | <b>APSR</b> , <b>EPSR</b> , and <b>IPSR</b> |
| <b>IEPSR</b> | RO                  | <b>EPSR</b> and <b>IPSR</b>                 |
| <b>IAPSR</b> | R/W <sup>a</sup>    | <b>APSR</b> and <b>IPSR</b>                 |
| <b>EAPSR</b> | R/W <sup>b</sup>    | <b>APSR</b> and <b>EPSR</b>                 |

a. The processor ignores writes to the **IPSR** bits.

b. Reads of the **EPSR** bits return zero, and the processor ignores writes to these bits.

**Program Status Register (PSR)**

Type R/W, reset 0x0100.0000

See "Exception Types" on page 103 for more information.

The value of this field is only meaningful when accessing **PSR** or **IPSR**.

Register 18: Priority Mask Register (PRIMASK)

The **PRIMASK** register prevents activation of all exceptions with programmable priority. Reset, non-maskable interrupt (NMI), and hard fault are the only exceptions with fixed priority. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The MSR and MRS instructions are used to access the **PRIMASK** register, and the CPS instruction may be used to change the value of the **PRIMASK** register. See the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 103.

Priority Mask Register (PRIMASK)

Type R/W, reset 0x0000.0000

## Register 19: Fault Mask Register (FAULTMASK)

The **FAULTMASK** register prevents activation of all exceptions except for the Non-Maskable Interrupt (NMI). Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The MSR and MRS instructions are used to access the **FAULTMASK** register, and the CPS instruction may be used to change the value of the **FAULTMASK** register. See the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 103.

### Fault Mask Register (FAULTMASK)

Type R/W, reset 0x0000.0000

|-----------|-----------|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:1      | reserved  | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | FAULTMASK | R/W  | 0          | Fault Mask                                                                                                                                                                                    |

#### Value Description

|   |                                                           |
|---|-----------------------------------------------------------|
| 1 | Prevents the activation of all exceptions except for NMI. |
| 0 | No effect.                                                |

The processor clears the FAULTMASK bit on exit from any exception handler except the NMI handler.

**Register 20: Base Priority Mask Register (BASEPRI)**

The **BASEPRI** register defines the minimum priority for exception processing. When **BASEPRI** is set to a nonzero value, it prevents the activation of all exceptions with the same or lower priority level as the **BASEPRI** value. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. For more information on exception priority levels, see “Exception Types” on page 103.

## Register 21: Control Register (CONTROL)

The **CONTROL** register controls the stack used and the privilege level for software execution when the processor is in Thread mode, and indicates whether the FPU state is active. This register is only accessible in privileged mode.

Handler mode always uses **MSP**, so the processor ignores explicit writes to the ASP bit of the **CONTROL** register when in Handler mode. The exception entry and return mechanisms automatically update the **CONTROL** register based on the EXC\_RETURN value (see Table 2-10 on page 112). In an OS environment, threads running in Thread mode should use the process stack and the kernel and exception handlers should use the main stack. By default, Thread mode uses **MSP**. To switch the stack pointer used in Thread mode to **PSP**, either use the MSR instruction to set the ASP bit, as detailed in the *Cortex™-M3/M4 Instruction Set Technical User's Manual*, or perform an exception return to Thread mode with the appropriate EXC\_RETURN value, as shown in Table 2-10 on page 112.

**Note:** When changing the stack pointer, software must use an ISB instruction immediately after the MSR instruction, ensuring that instructions after the ISB execute use the new stack pointer. See the *Cortex™-M3/M4 Instruction Set Technical User's Manual*.

### Control Register (CONTROL)

Type R/W, reset 0x0000.0000

|           | 0        | No floating-point context active |            |                                                                                                                                                                                               |

The Cortex-M4F uses this bit to determine whether to preserve floating-point state when processing an exception.

**Important:** Two bits control when FPCA can be enabled: the ASPEN bit in the **Floating-Point Context Control (FPCC)** register and the DISFPCA bit in the **Auxiliary Control (ACTLR)** register.

| Bit/Field | Name | Type | Reset | Description                                                                                                                                                                                                                                                                                   |

## Register 22: Floating-Point Status Control (FPSC)

The **FPSC** register provides all necessary user-level control of the floating-point system.

### Floating-Point Status Control (FPSC)

Type R/W, reset -

### 2.3.5 Exceptions and Interrupts

The Cortex-M4F processor supports interrupts and system exceptions. The processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. An exception changes the normal flow of software control. The processor uses Handler mode to handle all exceptions except for reset. See “Exception Entry and Return” on page 109 for more information.

The NVIC registers control interrupt handling. See “Nested Vectored Interrupt Controller (NVIC)” on page 125 for more information.

### 2.3.6 Data Types

The Cortex-M4F supports 32-bit words, 16-bit halfwords, and 8-bit bytes. The processor also supports 64-bit data transfer instructions. All instruction and data memory accesses are little endian. See “Memory Regions, Types and Attributes” on page 96 for more information.

## 2.4 Memory Model

This section describes the processor memory map, the behavior of memory accesses, and the bit-banding features. The processor has a fixed memory map that provides up to 4 GB of addressable memory.

The memory map for the LM4F231H5QR controller is provided in Table 2-4 on page 93. In this manual, register addresses are given as a hexadecimal increment, relative to the module’s base address as shown in the memory map.

The regions for SRAM and peripherals include bit-band regions. Bit-banding provides atomic operations to bit data (see “Bit-Banding” on page 98).

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers (see “Cortex-M4 Peripherals” on page 123).

**Note:** Within the memory map, all reserved space returns a bus fault when read or written.

**Table 2-4. Memory Map**

### 2.4.1 Memory Regions, Types and Attributes

The memory map and the programming of the MPU split the memory map into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

- Normal: The processor can re-order transactions for efficiency and perform speculative reads.
- Device: The processor preserves transaction order relative to other transactions to Device or Strongly Ordered memory.
- Strongly Ordered: The processor preserves transaction order relative to all other transactions.

The different ordering requirements for Device and Strongly Ordered memory mean that the memory system can buffer a write to Device memory but must not buffer a write to Strongly Ordered memory.

An additional memory attribute is Execute Never (XN), which means the processor prevents instruction accesses. A fault exception is generated only on execution of an instruction executed from an XN region.

### 2.4.2 Memory System Ordering of Memory Accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing the order does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions (see “Software Ordering of Memory Accesses” on page 97).

However, the memory system does guarantee ordering of accesses to Device and Strongly Ordered memory. For two memory access instructions A1 and A2, if both A1 and A2 are accesses to either Device or Strongly Ordered memory, and if A1 occurs before A2 in program order, A1 is always observed before A2.

### 2.4.3 Behavior of Memory Accesses

Table 2-5 on page 96 shows the behavior of accesses to each region in the memory map. See “Memory Regions, Types and Attributes” on page 96 for more information on memory types and the XN attribute. Stellaris devices may have reserved memory areas within the address ranges shown below (refer to Table 2-4 on page 93 for more information).

**Table 2-5. Memory Access Behavior**

| Address Range             | Memory Region | Memory Type | Execute Never (XN) | Description                                                                                                                                          |
|---------------------------|---------------|-------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0000.0000 - 0x1FFF.FFFF | Code          | Normal      | -                  | This executable region is for program code. Data can also be stored here.                                                                            |
| 0x2000.0000 - 0x3FFF.FFFF | SRAM          | Normal      | -                  | This executable region is for data. Code can also be stored here. This region includes bit band and bit band alias areas (see Table 2-6 on page 98). |
| 0x4000.0000 - 0x5FFF.FFFF | Peripheral    | Device      | XN                 | This region includes bit band and bit band alias areas (see Table 2-7 on page 99).                                                                   |
| 0x6000.0000 - 0x9FFF.FFFF | External RAM  | Normal      | -                  | This executable region is for data.                                                                                                                  |

**Table 2-5. Memory Access Behavior (continued)**

| Address Range             | Memory Region          | Memory Type      | Execute Never (XN) | Description                                                            |
|---------------------------|------------------------|------------------|--------------------|------------------------------------------------------------------------|
| 0xA000.0000 - 0xDFFF.FFFF | External device        | Device           | XN                 | This region is for external device memory.                             |
| 0xE000.0000- 0xE00F.FFFF  | Private peripheral bus | Strongly Ordered | XN                 | This region includes the NVIC, system timer, and system control block. |
| 0xE010.0000- 0xFFFF.FFFF  | Reserved               | -                | -                  | -                                                                      |

The Code, SRAM, and external RAM regions can hold programs. However, it is recommended that programs always use the Code region because the Cortex-M4F has separate buses that can perform instruction fetches and data accesses simultaneously.

The MPU can override the default memory access behavior described in this section. For more information, see “Memory Protection Unit (MPU)” on page 126.

The Cortex-M4F prefetches instructions ahead of execution and speculatively prefetches from branch target addresses.

#### 2.4.4 Software Ordering of Memory Accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions for the following reasons:

- The processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- The processor has multiple bus interfaces.
- Memory or devices in the memory map have different wait states.
- Some memory accesses are buffered or speculative.

“Memory System Ordering of Memory Accesses” on page 96 describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The Cortex-M4F has the following memory barrier instructions:

- The Data Memory Barrier (DMB) instruction ensures that outstanding memory transactions complete before subsequent memory transactions.
- The Data Synchronization Barrier (DSB) instruction ensures that outstanding memory transactions complete before subsequent instructions execute.
- The Instruction Synchronization Barrier (ISB) instruction ensures that the effect of all completed memory transactions is recognizable by subsequent instructions.

Memory barrier instructions can be used in the following situations:

- MPU programming
  - If the MPU settings are changed and the change must be effective on the very next instruction, use a DSB instruction to ensure the effect of the MPU takes place immediately at the end of context switching.

- Use an ISB instruction to ensure the new MPU setting takes effect immediately after programming the MPU region or regions, if the MPU configuration code was accessed using a branch or call. If the MPU configuration code is entered using exception mechanisms, then an ISB instruction is not required.

- Vector table

If the program changes an entry in the vector table and then enables the corresponding exception, use a DMB instruction between the operations. The DMB instruction ensures that if the exception is taken immediately after being enabled, the processor uses the new exception vector.

- Self-modifying code

If a program contains self-modifying code, use an ISB instruction immediately after the code modification in the program. The ISB instruction ensures subsequent instruction execution uses the updated program.

- Memory map switching

If the system contains a memory map switching mechanism, use a DSB instruction after switching the memory map in the program. The DSB instruction ensures subsequent instruction execution uses the updated memory map.

- Dynamic exception priority change

When an exception priority has to change when the exception is pending or active, use DSB instructions after the change. The change then takes effect on completion of the DSB instruction.

Memory accesses to Strongly Ordered memory, such as the System Control Block, do not require the use of DMB instructions.

For more information on the memory barrier instructions, see the *Cortex™-M3/M4 Instruction Set Technical User's Manual*.

## 2.4.5 Bit-Banding

A bit-band region maps each word in a bit-band alias region to a single bit in the bit-band region. The bit-band regions occupy the lowest 1 MB of the SRAM and peripheral memory regions. Accesses to the 32-MB SRAM alias region map to the 1-MB SRAM bit-band region, as shown in Table 2-6 on page 98. Accesses to the 32-MB peripheral alias region map to the 1-MB peripheral bit-band region, as shown in Table 2-7 on page 99. For the specific address range of the bit-band regions, see Table 2-4 on page 93.

**Note:** A word access to the SRAM or the peripheral bit-band alias region maps to a single bit in the SRAM or peripheral bit-band region.

A word access to a bit band address results in a word access to the underlying memory, and similarly for halfword and byte accesses. This allows bit band accesses to match the access requirements of the underlying peripheral.

**Table 2-6. SRAM Memory Bit-Banding Regions**

| Address Range             | Memory Region        | Instruction and Data Accesses                                                                                                        |
|---------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 0x2000.0000 - 0x200F.FFFF | SRAM bit-band region | Direct accesses to this memory range behave as SRAM memory accesses, but this region is also bit addressable through bit-band alias. |

**Table 2-6. SRAM Memory Bit-Banding Regions (continued)**

| Address Range             | Memory Region       | Instruction and Data Accesses                                                                                                                             |
|---------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x2200.0000 - 0x23FF.FFFF | SRAM bit-band alias | Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not remapped. |

**Table 2-7. Peripheral Memory Bit-Banding Regions**

| Address Range             | Memory Region              | Instruction and Data Accesses                                                                                                                              |
|---------------------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x4000.0000 - 0x400F.FFFF | Peripheral bit-band region | Direct accesses to this memory range behave as peripheral memory accesses, but this region is also bit addressable through bit-band alias.                 |
| 0x4200.0000 - 0x43FF.FFFF | Peripheral bit-band alias  | Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not permitted. |

The following formula shows how the alias region maps onto the bit-band region:

$$\text{bit\_word\_offset} = (\text{byte\_offset} \times 32) + (\text{bit\_number} \times 4)$$

$$\text{bit\_word\_addr} = \text{bit\_band\_base} + \text{bit\_word\_offset}$$

where:

**bit\_word\_offset**

The position of the target bit in the bit-band memory region.

**bit\_word\_addr**

The address of the word in the alias memory region that maps to the targeted bit.

**bit\_band\_base**

The starting address of the alias region.

**byte\_offset**

The number of the byte in the bit-band region that contains the targeted bit.

**bit\_number**

The bit position, 0-7, of the targeted bit.

Figure 2-4 on page 100 shows examples of bit-band mapping between the SRAM bit-band alias region and the SRAM bit-band region:

- The alias word at 0x23FF.FFE0 maps to bit 0 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFE0 = 0x2200.0000 + (0x000F.FFFF \times 32) + (0 \times 4)$$

- The alias word at 0x23FF.FFFC maps to bit 7 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFFC = 0x2200.0000 + (0x000F.FFFF \times 32) + (7 \times 4)$$

- The alias word at 0x2200.0000 maps to bit 0 of the bit-band byte at 0x2000.0000:

$$0x2200.0000 = 0x2200.0000 + (0 \times 32) + (0 \times 4)$$

- The alias word at 0x2200.001C maps to bit 7 of the bit-band byte at 0x2000.0000:

$$0x2200.001C = 0x2200.0000 + (0 \times 32) + (7 \times 4)$$

Figure 2-4. Bit-Band Mapping

#### 2.4.5.1 Directly Accessing an Alias Region

Writing to a word in the alias region updates a single bit in the bit-band region.

Bit 0 of the value written to a word in the alias region determines the value written to the targeted bit in the bit-band region. Writing a value with bit 0 set writes a 1 to the bit-band bit, and writing a value with bit 0 clear writes a 0 to the bit-band bit.

Bits 31:1 of the alias word have no effect on the bit-band bit. Writing 0x01 has the same effect as writing 0xFF. Writing 0x00 has the same effect as writing 0x0E.

When reading a word in the alias region, 0x0000.0000 indicates that the targeted bit in the bit-band region is clear and 0x0000.0001 indicates that the targeted bit in the bit-band region is set.

#### 2.4.5.2 Directly Accessing a Bit-Band Region

“Behavior of Memory Accesses” on page 96 describes the behavior of direct byte, halfword, or word accesses to the bit-band regions.

### 2.4.6 Data Storage

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. Data is stored in little-endian format, with the least-significant byte (lsbyte) of a word stored at the lowest-numbered byte, and the most-significant byte (msbyte) stored at the highest-numbered byte. Figure 2-5 on page 101 illustrates how data is stored.

**Figure 2-5. Data Storage**

### 2.4.7 Synchronization Primitives

The Cortex-M4F instruction set includes pairs of synchronization primitives which provide a non-blocking mechanism that a thread or process can use to obtain exclusive access to a memory location. Software can use these primitives to perform a guaranteed read-modify-write memory update sequence or for a semaphore mechanism.

A pair of synchronization primitives consists of:

- A Load-Exclusive instruction, which is used to read the value of a memory location and requests exclusive access to that location.
- A Store-Exclusive instruction, which is used to attempt to write to the same memory location and returns a status bit to a register. If this status bit is clear, it indicates that the thread or process gained exclusive access to the memory and the write succeeds; if this status bit is set, it indicates that the thread or process did not gain exclusive access to the memory and no write was performed.

The pairs of Load-Exclusive and Store-Exclusive instructions are:

- The word instructions LDREX and STREX
- The halfword instructions LDREXH and STREXH
- The byte instructions LDREXB and STREXB

Software must use a Load-Exclusive instruction with the corresponding Store-Exclusive instruction.

To perform an exclusive read-modify-write of a memory location, software must:

1. Use a Load-Exclusive instruction to read the value of the location.
2. Modify the value, as required.
3. Use a Store-Exclusive instruction to attempt to write the new value back to the memory location.
4. Test the returned status bit.

If the status bit is clear, the read-modify-write completed successfully. If the status bit is set, no write was performed, which indicates that the value returned at step 1 might be out of date. The software must retry the entire read-modify-write sequence.

Software can use the synchronization primitives to implement a semaphore as follows:

1. Use a Load-Exclusive instruction to read from the semaphore address to check whether the semaphore is free.
2. If the semaphore is free, use a Store-Exclusive to write the claim value to the semaphore address.
3. If the returned status bit from step 2 indicates that the Store-Exclusive succeeded, then the software has claimed the semaphore. However, if the Store-Exclusive failed, another process might have claimed the semaphore after the software performed step 1.

The Cortex-M4F includes an exclusive access monitor that tags the fact that the processor has executed a Load-Exclusive instruction. The processor removes its exclusive access tag if:

- It executes a CLREX instruction.
- It executes a Store-Exclusive instruction, regardless of whether the write succeeds.
- An exception occurs, which means the processor can resolve semaphore conflicts between different threads.

For more information about the synchronization primitive instructions, see the *Cortex™-M3/M4 Instruction Set Technical User's Manual*.

## 2.5 Exception Model

The ARM Cortex-M4F processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 2-8 on page 104 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 80 interrupts (listed in Table 2-9 on page 105).

Priorities on the system handlers are set with the NVIC **System Handler Priority n (SYSPRIn)** registers. Interrupts are enabled through the NVIC **Interrupt Set Enable n (ENn)** register and prioritized with the NVIC **Interrupt Priority n (PRIn)** registers. Priorities can be grouped by splitting priority levels into preemption priorities and subpriorities. All the interrupt registers are described in “Nested Vectored Interrupt Controller (NVIC)” on page 125.

Internally, the highest user-programmable priority (0) is treated as fourth priority, after a Reset, Non-Maskable Interrupt (NMI), and a Hard Fault, in that order. Note that 0 is the default priority for all the programmable priorities.

---

**Important:** After a write to clear an interrupt source, it may take several processor cycles for the NVIC to see the interrupt source de-assert. Thus if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while the NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This situation can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer).

---

See “Nested Vectored Interrupt Controller (NVIC)” on page 125 for more information on exceptions and interrupts.

## 2.5.1 Exception States

Each exception is in one of the following states:

- **Inactive.** The exception is not active and not pending.
- **Pending.** The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending.
- **Active.** An exception that is being serviced by the processor but has not completed.  
**Note:** An exception handler can interrupt the execution of another exception handler. In this case, both exceptions are in the active state.
- **Active and Pending.** The exception is being serviced by the processor, and there is a pending exception from the same source.

## 2.5.2 Exception Types

The exception types are:

- **Reset.** Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts as privileged execution in Thread mode.
- **NMI.** A non-maskable Interrupt (NMI) can be signaled using the NMI signal or triggered by software using the **Interrupt Control and State (INTCTRL)** register. This exception has the highest priority other than reset. NMI is permanently enabled and has a fixed priority of -2. NMIs cannot be masked or prevented from activation by any other exception or preempted by any exception other than reset.
- **Hard Fault.** A hard fault is an exception that occurs because of an error during exception processing, or because an exception cannot be managed by any other exception mechanism. Hard faults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority.
- **Memory Management Fault.** A memory management fault is an exception that occurs because of a memory protection related fault, including access violation and no match. The MPU or the fixed memory protection constraints determine this fault, for both instruction and data memory transactions. This fault is used to abort instruction accesses to Execute Never (XN) memory regions, even if the MPU is disabled.
- **Bus Fault.** A bus fault is an exception that occurs because of a memory-related fault for an instruction or data memory transaction such as a prefetch fault or a memory access fault. This fault can be enabled or disabled.
- **Usage Fault.** A usage fault is an exception that occurs because of a fault related to instruction execution, such as:
  - An undefined instruction
  - An illegal unaligned access
  - Invalid state on instruction execution

- An error on exception return

An unaligned address on a word or halfword memory access or division by zero can cause a usage fault when the core is properly configured.

- **SVC**all. A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers.
- **Debug Monitor**. This exception is caused by the debug monitor (when not halting). This exception is only active when enabled. This exception does not activate if it is a lower priority than the current activation.
- **PendSV**. PendSV is a pendable, interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active. PendSV is triggered using the **Interrupt Control and State (INTCTRL)** register.
- **SysTick**. A SysTick exception is an exception that the system timer generates when it reaches zero when it is enabled to generate an interrupt. Software can also generate a SysTick exception using the **Interrupt Control and State (INTCTRL)** register. In an OS environment, the processor can use this exception as system tick.
- **Interrupt (IRQ)**. An interrupt, or IRQ, is an exception signaled by a peripheral or generated by a software request and fed through the NVIC (prioritized). All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor. Table 2-9 on page 105 lists the interrupts on the LM4F231H5QR controller.

For an asynchronous exception, other than reset, the processor can execute another instruction between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that Table 2-8 on page 104 shows as having configurable priority (see the **SYSHNDCTRL** register on page 174 and the **DIS0** register on page 145).

For more information about hard faults, memory management faults, bus faults, and usage faults, see “Fault Handling” on page 112.

**Table 2-8. Exception Types**

| Exception Type               | Vector Number | Priority <sup>a</sup>     | Vector Address or Offset <sup>b</sup> | Activation                                                             |
|------------------------------|---------------|---------------------------|---------------------------------------|------------------------------------------------------------------------|
| -                            | 0             | -                         | 0x0000.0000                           | Stack top is loaded from the first entry of the vector table on reset. |
| Reset                        | 1             | -3 (highest)              | 0x0000.0004                           | Asynchronous                                                           |
| Non-Maskable Interrupt (NMI) | 2             | -2                        | 0x0000.0008                           | Asynchronous                                                           |
| Hard Fault                   | 3             | -1                        | 0x0000.000C                           | -                                                                      |
| Memory Management            | 4             | programmable <sup>c</sup> | 0x0000.0010                           | Synchronous                                                            |
| Bus Fault                    | 5             | programmable <sup>c</sup> | 0x0000.0014                           | Synchronous when precise and asynchronous when imprecise               |
| Usage Fault                  | 6             | programmable <sup>c</sup> | 0x0000.0018                           | Synchronous                                                            |
| -                            | 7-10          | -                         | -                                     | Reserved                                                               |
| SVCall                       | 11            | programmable <sup>c</sup> | 0x0000.002C                           | Synchronous                                                            |
| Debug Monitor                | 12            | programmable <sup>c</sup> | 0x0000.0030                           | Synchronous                                                            |
| -                            | 13            | -                         | -                                     | Reserved                                                               |

**Table 2-8. Exception Types (continued)**

| Exception Type | Vector Number | Priority <sup>a</sup>     | Vector Address or Offset <sup>b</sup> | Activation   |
|----------------|---------------|---------------------------|---------------------------------------|--------------|
| PendSV         | 14            | programmable <sup>c</sup> | 0x0000.0038                           | Asynchronous |
| SysTick        | 15            | programmable <sup>c</sup> | 0x0000.003C                           | Asynchronous |
| Interrupts     | 16 and above  | programmable <sup>d</sup> | 0x0000.0040 and above                 | Asynchronous |

a. 0 is the default priority for all the programmable priorities.

b. See "Vector Table" on page 107.

c. See **SYSPRI1** on page 171.

d. See **PRIn** registers on page 153.

**Table 2-9. Interrupts**

| Vector Number | Interrupt Number (Bit in Interrupt Registers) | Vector Address or Offset  | Description             |
|---------------|-----------------------------------------------|---------------------------|-------------------------|
| 0-15          | -                                             | 0x0000.0000 - 0x0000.003C | Processor exceptions    |
| 16            | 0                                             | 0x0000.0040               | GPIO Port A             |
| 17            | 1                                             | 0x0000.0044               | GPIO Port B             |
| 18            | 2                                             | 0x0000.0048               | GPIO Port C             |
| 19            | 3                                             | 0x0000.004C               | GPIO Port D             |
| 20            | 4                                             | 0x0000.0050               | GPIO Port E             |
| 21            | 5                                             | 0x0000.0054               | UART0                   |

| 126           | 110                                           | 0x0000.01F8              | I <sup>2</sup> C5            |
| 127-149       | 111-133                                       | -                        | Reserved                     |
| 150           | 134                                           | 0x0000.0258              | PWM1 Generator 0             |
| 151           | 135                                           | 0x0000.025C              | PWM1 Generator 1             |
| 152           | 136                                           | 0x0000.0260              | PWM1 Generator 2             |
| 153           | 137                                           | 0x0000.0264              | PWM1 Generator 3             |
| 154           | 138                                           | 0x0000.0268              | PWM1 Fault                   |

### 2.5.3 Exception Handlers

The processor handles exceptions using:

- **Interrupt Service Routines (ISRs).** Interrupts (IRQx) are the exceptions handled by ISRs.
- **Fault Handlers.** Hard fault, memory management fault, usage fault, and bus fault are fault exceptions handled by the fault handlers.
- **System Handlers.** NMI, PendSV, SVCcall, SysTick, and the fault exceptions are all system exceptions that are handled by system handlers.

### 2.5.4 Vector Table

The vector table contains the reset value of the stack pointer and the start addresses, also called exception vectors, for all exception handlers. The vector table is constructed using the vector address or offset shown in Table 2-8 on page 104. Figure 2-6 on page 108 shows the order of the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is Thumb code

**Figure 2-6. Vector Table**

| Exception number | IRQ number | Offset | Vector                  |
|------------------|------------|--------|-------------------------|
| 154              | 138        | 0x0268 | IRQ131                  |
| .                | .          | .      | .                       |
| .                | .          | .      | .                       |
| .                | .          | .      | .                       |
| 18               | 2          | 0x004C | IRQ2                    |
| 17               | 1          | 0x0048 | IRQ1                    |
| 16               | 0          | 0x0044 | IRQ0                    |
| 15               | -1         | 0x0040 | Systick                 |
| 14               | -2         | 0x003C | PendSV                  |
| 13               |            | 0x0038 | Reserved                |
| 12               |            |        | Reserved for Debug      |
| 11               | -5         | 0x002C | SVCall                  |
| 10               |            |        | Reserved                |
| 9                |            |        |                         |
| 8                |            |        |                         |
| 7                |            |        |                         |
| 6                | -10        | 0x0018 | Usage fault             |
| 5                | -11        | 0x0014 | Bus fault               |
| 4                | -12        | 0x0010 | Memory management fault |
| 3                | -13        | 0x000C | Hard fault              |
| 2                | -14        | 0x0008 | NMI                     |
| 1                |            | 0x0004 | Reset                   |
|                  |            | 0x0000 | Initial SP value        |

On system reset, the vector table is fixed at address 0x0000.0000. Privileged software can write to the **Vector Table Offset (VTABLE)** register to relocate the vector table start address to a different memory location, in the range 0x0000.0400 to 0x3FFF.FC00 (see “Vector Table” on page 107). Note that when configuring the **VTABLE** register, the offset must be aligned on a 1024-byte boundary.

### 2.5.5 Exception Priorities

As Table 2-8 on page 104 shows, all exceptions have an associated priority, with a lower priority value indicating a higher priority and configurable priorities for all exceptions except Reset, Hard fault, and NMI. If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities, see page 171 and page 153.

**Note:** Configurable priority values for the Stellaris implementation are in the range 0-7. This means that the Reset, Hard fault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

### 2.5.6 Interrupt Priority Grouping

To increase priority control in systems with interrupts, the NVIC supports priority grouping. This grouping divides each interrupt priority register entry into two fields:

- An upper field that defines the group priority
- A lower field that defines a subpriority within the group

Only the group priority determines preemption of interrupt exceptions. When the processor is executing an interrupt exception handler, another interrupt with the same group priority as the interrupt being handled does not preempt the handler.

If multiple pending interrupts have the same group priority, the subpriority field determines the order in which they are processed. If multiple pending interrupts have the same group priority and subpriority, the interrupt with the lowest IRQ number is processed first.

For information about splitting the interrupt priority fields into group priority and subpriority, see page 165.

### 2.5.7 Exception Entry and Return

Descriptions of exception handling use the following terms:

- **Preemption.** When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. See “Interrupt Priority Grouping” on page 109 for more information about preemption by an interrupt. When one exception preempts another, the exceptions are called nested exceptions. See “Exception Entry” on page 110 for more information.
- **Return.** Return occurs when the exception handler is completed, and there is no pending exception with sufficient priority to be serviced and the completed exception handler was not handling a late-arriving exception. The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See “Exception Return” on page 111 for more information.
- **Tail-Chaining.** This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.
- **Late-Arriving.** This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved is the same for both exceptions. Therefore, the state saving continues uninterrupted. The processor can accept a late arriving exception until the first instruction of the exception handler of the original exception enters the execute stage of the processor. On

return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

#### 2.5.7.1 Exception Entry

Exception entry occurs when there is a pending exception with sufficient priority and either the processor is in Thread mode or the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has more priority than any limits set by the mask registers (see **PRIMASK** on page 86, **FAULTMASK** on page 87, and **BASEPRI** on page 88). An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as *stacking* and the structure of eight data words is referred to as *stack frame*.

When using floating-point routines, the Cortex-M4F processor automatically stacks the architected floating-point state on exception entry. Figure 2-7 on page 111 shows the Cortex-M4F stack frame layout when floating-point state is preserved on the stack as the result of an interrupt or an exception.

**Note:** Where stack space for floating-point state is not allocated, the stack frame is the same as that of ARMv7-M implementations without an FPU. Figure 2-7 on page 111 shows this stack frame also.

**Figure 2-7. Exception Stack Frame**

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame.

The stack frame includes the return address, which is the address of the next instruction in the interrupted program. This value is restored to the **PC** at exception return so that the interrupted program resumes.

In parallel to the stacking operation, the processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an **EXC\_RETURN** value to the **LR**, indicating which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher-priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

If another higher-priority exception occurs during exception entry, known as late arrival, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception.

### 2.5.7.2 Exception Return

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the **EXC\_RETURN** value into the **PC**:

- An LDM or POP instruction that loads the **PC**
- A BX instruction using any register
- An LDR instruction with the **PC** as the destination

EXC\_RETURN is the value loaded into the **LR** on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The lowest five bits of this value provide information on the return stack and processor mode. Table 2-10 on page 112 shows the EXC\_RETURN values with a description of the exception return behavior.

EXC\_RETURN bits 31:5 are all set. When this value is loaded into the **PC**, it indicates to the processor that the exception is complete, and the processor initiates the appropriate exception return sequence.

**Table 2-10. Exception Return Behavior**

| EXC_RETURN[31:0]          | Description                                                                                                                            |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------|

## 2.6 Fault Handling

Faults are a subset of the exceptions (see “Exception Model” on page 102). The following conditions generate a fault:

- A bus error on an instruction fetch or vector table load or a data access.

- An internally detected error such as an undefined instruction or an attempt to change state with a BX instruction.
- Attempting to execute an instruction from a memory region marked as Non-Executable (XN).
- An MPU fault because of a privilege violation or an attempt to access an unmanaged region.

## 2.6.1 Fault Types

Table 2-11 on page 113 shows the types of fault, the handler used for the fault, the corresponding fault status register, and the register bit that indicates the fault has occurred. See page 178 for more information about the fault status registers.

**Table 2-11. Faults**

| Fault                                                                        | Handler                 | Fault Status Register                              | Bit Name          |
|------------------------------------------------------------------------------|-------------------------|----------------------------------------------------|-------------------|
| Bus error on a vector read                                                   | Hard fault              | <b>Hard Fault Status (HFAULTSTAT)</b>              | VECT              |
| Fault escalated to a hard fault                                              | Hard fault              | <b>Hard Fault Status (HFAULTSTAT)</b>              | FORCED            |
| MPU or default memory mismatch on instruction access                         | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | IERR <sup>a</sup> |
| MPU or default memory mismatch on data access                                | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | DERR              |
| MPU or default memory mismatch on exception stacking                         | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | MSTKE             |
| MPU or default memory mismatch on exception unstacking                       | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | MUSTKE            |
| MPU or default memory mismatch during lazy floating-point state preservation | Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | MLSPERR           |
| Bus error during exception stacking                                          | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | BSTKE             |
| Bus error during exception unstacking                                        | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | BUSTKE            |
| Bus error during instruction prefetch                                        | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | IBUS              |
| Bus error during lazy floating-point state preservation                      | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | BLSPE             |
| Precise data bus error                                                       | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | PRECISE           |
| Imprecise data bus error                                                     | Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | IMPRE             |
| Attempt to access a coprocessor                                              | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | NOCP              |
| Undefined instruction                                                        | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | UNDEF             |
| Attempt to enter an invalid instruction set state <sup>b</sup>               | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | INVSTAT           |
| Invalid EXC_RETURN value                                                     | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | INVPC             |
| Illegal unaligned load or store                                              | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | UNALIGN           |
| Divide by 0                                                                  | Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | DIV0              |

a. Occurs on an access to an XN region even if the MPU is disabled.

b. Attempting to use an instruction set other than the Thumb instruction set, or returning to a non load-store-multiple instruction with ICI continuation.

## 2.6.2 Fault Escalation and Hard Faults

All fault exceptions except for hard fault have configurable exception priority (see **SYSPRI1** on page 171). Software can disable execution of the handlers for these faults (see **SYSHNDCTRL** on page 174).

Usually, the exception priority, together with the values of the exception mask registers, determines whether the processor enters the fault handler, and whether a fault handler can preempt another fault handler as described in “Exception Model” on page 102.

In some situations, a fault with configurable priority is treated as a hard fault. This process is called priority escalation, and the fault is described as *escalated to hard fault*. Escalation to hard fault occurs when:

- A fault handler causes the same kind of fault as the one it is servicing. This escalation to hard fault occurs because a fault handler cannot preempt itself because it must have the same priority as the current priority level.
- A fault handler causes a fault with the same or lower priority as the fault it is servicing. This situation happens because the handler for the new fault cannot preempt the currently executing fault handler.
- An exception handler causes a fault for which the priority is the same as or lower than the currently executing exception.
- A fault occurs and the handler for that fault is not enabled.

If a bus fault occurs during a stack push when entering a bus fault handler, the bus fault does not escalate to a hard fault. Thus if a corrupted stack causes a fault, the fault handler executes even though the stack push for the handler failed. The fault handler operates but the stack contents are corrupted.

**Note:** Only Reset and NMI can preempt the fixed priority hard fault. A hard fault can preempt any exception other than Reset, NMI, or another hard fault.

### 2.6.3 Fault Status Registers and Fault Address Registers

The fault status registers indicate the cause of a fault. For bus faults and memory management faults, the fault address register indicates the address accessed by the operation that caused the fault, as shown in Table 2-12 on page 114.

**Table 2-12. Fault Status and Fault Address Registers**

| Handler                 | Status Register Name                               | Address Register Name                           | Register Description |
|-------------------------|----------------------------------------------------|-------------------------------------------------|----------------------|
| Hard fault              | <b>Hard Fault Status (HFAULTSTAT)</b>              | -                                               | page 184             |
| Memory management fault | <b>Memory Management Fault Status (MFAULTSTAT)</b> | <b>Memory Management Fault Address (MMADDR)</b> | page 178<br>page 185 |
| Bus fault               | <b>Bus Fault Status (BFAULTSTAT)</b>               | <b>Bus Fault Address (FAULTADDR)</b>            | page 178<br>page 186 |
| Usage fault             | <b>Usage Fault Status (UFAULTSTAT)</b>             | -                                               | page 178             |

### 2.6.4 Lockup

The processor enters a lockup state if a hard fault occurs when executing the NMI or hard fault handlers. When the processor is in the lockup state, it does not execute any instructions. The processor remains in lockup state until it is reset, an NMI occurs, or it is halted by a debugger.

**Note:** If the lockup state occurs from the NMI handler, a subsequent NMI does not cause the processor to leave the lockup state.

## 2.7 Power Management

The Cortex-M4F processor sleep modes reduce power consumption:

- Sleep mode stops the processor clock.
- Deep-sleep mode stops the system clock and switches off the PLL and Flash memory.

The SLEEPDEEP bit of the **System Control (SYSCTRL)** register selects which sleep mode is used (see page 167). For more information about the behavior of the sleep modes, see “System Control” on page 227.

This section describes the mechanisms for entering sleep mode and the conditions for waking up from sleep mode, both of which apply to Sleep mode and Deep-sleep mode.

### 2.7.1 Entering Sleep Modes

This section describes the mechanisms software can use to put the processor into one of the sleep modes.

The system can generate spurious wake-up events, for example a debug operation wakes up the processor. Therefore, software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

#### 2.7.1.1 Wait for Interrupt

The wait for interrupt instruction, WFI, causes immediate entry to sleep mode unless the wake-up condition is true (see “Wake Up from WFI or Sleep-on-Exit” on page 116). When the processor executes a WFI instruction, it stops executing instructions and enters sleep mode. See the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information.

#### 2.7.1.2 Wait for Event

The wait for event instruction, WFE, causes entry to sleep mode conditional on the value of a one-bit event register. When the processor executes a WFE instruction, it checks the event register. If the register is 0, the processor stops executing instructions and enters sleep mode. If the register is 1, the processor clears the register and continues executing instructions without entering sleep mode.

If the event register is 1, the processor must not enter sleep mode on execution of a WFE instruction. Typically, this situation occurs if an SEV instruction has been executed. Software cannot access this register directly.

See the *Cortex™-M3/M4 Instruction Set Technical User's Manual* for more information.

#### 2.7.1.3 Sleep-on-Exit

If the SLEEPEXIT bit of the **SYSCTRL** register is set, when the processor completes the execution of all exception handlers, it returns to Thread mode and immediately enters sleep mode. This mechanism can be used in applications that only require the processor to run when an exception occurs.

### 2.7.2 Wake Up from Sleep Mode

The conditions for the processor to wake up depend on the mechanism that cause it to enter sleep mode.

### 2.7.2.1 Wake Up from WFI or Sleep-on-Exit

Normally, the processor wakes up only when the NVIC detects an exception with sufficient priority to cause exception entry. Some embedded systems might have to execute system restore tasks after the processor wakes up and before executing an interrupt handler. Entry to the interrupt handler can be delayed by setting the PRIMASK bit and clearing the FAULTMASK bit. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor clears PRIMASK. For more information about **PRIMASK** and **FAULTMASK**, see page 86 and page 87.

### 2.7.2.2 Wake Up from WFE

The processor wakes up if it detects an exception with sufficient priority to cause exception entry.

In addition, if the SEVONPEND bit in the **SYSCTRL** register is set, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about **SYSCTRL**, see page 167.

### 2.7.3 The Wake-Up Interrupt Controller

The Wake-Up Interrupt Controller (WIC) is a peripheral that can detect an interrupt and wake the processor from deep sleep mode. The WIC is enabled only when the DEEPSLEEP bit in the **SCR** register is set (see page 167).

The WIC is not programmable, and does not have any registers or user interface. It operates entirely from hardware signals.

When the WIC is enabled and the processor enters deep sleep mode, the power management unit in the system can power down most of the Cortex-M4F processor. This has the side effect of stopping the SysTick timer. When the WIC receives an interrupt, it takes a number of clock cycles to wake up the processor and restore its state, before it can process the interrupt. This means interrupt latency is increased in deep sleep mode.

**Note:** If the processor detects a connection to a debugger it disables the WIC.

## 2.8 Instruction Set Summary

The processor implements a version of the Thumb instruction set. Table 2-13 on page 116 lists the supported instructions.

**Note:** In Table 2-13 on page 116:

- Angle brackets, <>, enclose alternative forms of the operand
- Braces, {}, enclose optional operands
- The Operands column is not exhaustive
- Op2 is a flexible second operand that can be either a register or a constant
- Most instructions can use an optional condition code suffix

For more information on the instructions and operands, see the instruction descriptions in the *ARM® Cortex™-M4 Technical Reference Manual*.

**Table 2-13. Cortex-M4F Instruction Summary**

| Mnemonic  | Operands         | Brief Description | Flags      |
|-----------|------------------|-------------------|------------|
| ADC, ADCS | {Rd,} Rn, Op2    | Add with carry    | N, Z, C, V |
| ADD, ADDS | {Rd,} Rn, Op2    | Add               | N, Z, C, V |
| ADD, ADDW | {Rd,} Rn, #imm12 | Add               | -          |

Table 2-13. Cortex-M4F Instruction Summary (*continued*)

| Mnemonic      | Operands               | Brief Description                          | Flags      |
|---------------|------------------------|--------------------------------------------|------------|
| ADR           | Rd, label              | Load PC-relative address                   | -          |
| AND, ANDS     | {Rd,} Rn, Op2          | Logical AND                                | N, Z, C    |
| ASR, ASRS     | Rd, Rm, <Rs >#n        | Arithmetic shift right                     | N, Z, C    |
| B             | label                  | Branch                                     | -          |
| BFC           | Rd, #lsb, #width       | Bit field clear                            | -          |
| BFI           | Rd, Rn, #lsb, #width   | Bit field insert                           | -          |
| BIC, BICS     | {Rd,} Rn, Op2          | Bit clear                                  | N, Z, C    |
| BKPT          | #imm                   | Breakpoint                                 | -          |
| BL            | label                  | Branch with link                           | -          |
| BLX           | Rm                     | Branch indirect with link                  | -          |
| BX            | Rm                     | Branch indirect                            | -          |
| CBNZ          | Rn, label              | Compare and branch if non-zero             | -          |
| CBZ           | Rn, label              | Compare and branch if zero                 | -          |
| CLREX         | -                      | Clear exclusive                            | -          |

## 3 Cortex-M4 Peripherals

This chapter provides information on the Stellaris® implementation of the Cortex-M4 processor peripherals, including:

- SysTick (see page 124)  
Provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism.
- Nested Vectored Interrupt Controller (NVIC) (see page 125)
  - Facilitates low-latency exception and interrupt handling
  - Controls power management
  - Implements system control registers
- System Control Block (SCB) (see page 126)  
Provides system implementation information and system control, including configuration, control, and reporting of system exceptions.
- Memory Protection Unit (MPU) (see page 126)  
Supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.
- Floating-Point Unit (FPU) (see page 131)  
Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

Table 3-1 on page 123 shows the address map of the Private Peripheral Bus (PPB). Some peripheral register regions are split into two address regions, as indicated by two addresses listed.

**Table 3-1. Core Peripheral Register Regions**

| Address                                            | Core Peripheral                      | Description (see page ...) |
|----------------------------------------------------|--------------------------------------|----------------------------|

### 3.1 Functional Description

This chapter provides information on the Stellaris implementation of the Cortex-M4 processor peripherals: SysTick, NVIC, SCB and MPU.

### 3.1.1 System Timer (SysTick)

Cortex-M4 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example as:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNT bit in the **STCTRL** control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

The timer consists of three registers:

- **SysTick Control and Status (STCTRL)**: A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- **SysTick Reload Value (STRELOAD)**: The reload value for the counter, used to provide the counter's wrap value.
- **SysTick Current Value (STCURRENT)**: The current value of the counter.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the **STRELOAD** register on the next clock edge, then decrements on subsequent clocks. Clearing the **STRELOAD** register disables the counter on the next wrap. When the counter reaches zero, the COUNT status bit is set. The COUNT bit clears on reads.

Writing to the **STCURRENT** register clears the register and the COUNT status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

The SysTick counter runs on either the system clock or the precision internal oscillator (PIOSC) divided by 4. If this clock signal is stopped for low power mode, the SysTick counter stops. SysTick can be kept running during Deep-sleep mode by setting the CLK\_SRC bit in the **SysTick Control and Status Register (STCTRL)** register and ensuring that the PIOSCPD bit in the **Deep Sleep Clock Configuration (DSLPCLKCFG)** register is clear. Ensure software uses aligned word accesses to access the SysTick registers.

The SysTick counter reload and current value are undefined at reset; the correct initialization sequence for the SysTick counter is:

1. Program the value in the **STRELOAD** register.
2. Clear the **STCURRENT** register by writing to it with any value.
3. Configure the **STCTRL** register for the required operation.

**Note:** When the processor is halted for debugging, the counter does not decrement.

### 3.1.2 Nested Vectored Interrupt Controller (NVIC)

This section describes the Nested Vectored Interrupt Controller (NVIC) and the registers it uses. The NVIC supports:

- 80 interrupts.
- A programmable priority level of 0-7 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Low-latency exception and interrupt handling.
- Level and pulse detection of interrupt signals.
- Dynamic reprioritization of interrupts.
- Grouping of priority values into group priority and subpriority fields.
- Interrupt tail-chaining.
- An external Non-maskable interrupt (NMI).

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead, providing low latency exception handling.

#### 3.1.2.1 Level-Sensitive and Pulse Interrupts

The processor supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt (see “Hardware and Software Control of Interrupts” on page 125 for more information). For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. As a result, the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

#### 3.1.2.2 Hardware and Software Control of Interrupts

The Cortex-M4 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is High and the interrupt is not active.
- The NVIC detects a rising edge on the interrupt signal.
- Software writes to the corresponding interrupt set-pending register bit, or to the **Software Trigger Interrupt (SWTRIG)** register to make a Software-Generated Interrupt pending. See the INT bit in the **PEND0** register on page 147 or **SWTRIG** on page 157.

A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt, changing the state of the interrupt from pending to active. Then:
  - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.

If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.
- Software writes to the corresponding interrupt clear-pending register bit
  - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the state of the interrupt changes to inactive, if the state was pending or to active, if the state was active and pending.

### 3.1.3 System Control Block (SCB)

The System Control Block (SCB) provides system implementation information and system control, including configuration, control, and reporting of the system exceptions.

### 3.1.4 Memory Protection Unit (MPU)

This section describes the Memory protection unit (MPU). The MPU divides the memory map into a number of regions and defines the location, size, access permissions, and memory attributes of each region. The MPU supports independent attribute settings for each region, overlapping regions, and export of memory attributes to the system.

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M4 MPU defines eight separate memory regions, 0-7, and a background region.

When memory regions overlap, a memory access is affected by the attributes of the region with the highest number. For example, the attributes for region 7 take precedence over the attributes of any region that overlaps region 7.

The background region has the same memory access attributes as the default memory map, but is accessible from privileged software only.

The Cortex-M4 MPU memory map is unified, meaning that instruction accesses and data accesses have the same region settings.

If a program accesses a memory location that is prohibited by the MPU, the processor generates a memory management fault, causing a fault exception and possibly causing termination of the process in an OS environment. In an OS environment, the kernel can update the MPU region setting dynamically based on the process to be executed. Typically, an embedded OS uses the MPU for memory protection.

Configuration of MPU regions is based on memory types (see “Memory Regions, Types and Attributes” on page 96 for more information).

Table 3-2 on page 127 shows the possible MPU region attributes. See the section called “MPU Configuration for a Stellaris Microcontroller” on page 131 for guidelines for programming a microcontroller implementation.

**Table 3-2. Memory Attributes Summary**

| Memory Type      | Description                                                     |
|------------------|-----------------------------------------------------------------|
| Strongly Ordered | All accesses to Strongly Ordered memory occur in program order. |
| Device           | Memory-mapped peripherals                                       |
| Normal           | Normal memory                                                   |

To avoid unexpected behavior, disable the interrupts before updating the attributes of a region that the interrupt handlers might access.

Ensure software uses aligned accesses of the correct size to access MPU registers:

- Except for the **MPU Region Attribute and Size (MPUATTR)** register, all MPU registers must be accessed with aligned word accesses.
- The **MPUATTR** register can be accessed with byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to MPU registers.

When setting up the MPU, and if the MPU has previously been programmed, disable unused regions to prevent any previous region settings from affecting the new MPU setup.

### 3.1.4.1 Updating an MPU Region

To update the attributes for an MPU region, the **MPU Region Number (MPUNUMBER)**, **MPU Region Base Address (MPUBASE)** and **MPUATTR** registers must be updated. Each register can be programmed separately or with a multiple-word write to program all of these registers. You can use the **MPUBASEx** and **MPUATTRx** aliases to program up to four regions simultaneously using an STM instruction.

#### *Updating an MPU Region Using Separate Words*

This example simple code configures one region:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER      ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]      ; Region Number
STR R4, [R0, #0x4]      ; Region Base Address
STRH R2, [R0, #0x8]     ; Region Size and Enable
STRH R3, [R0, #0xA]     ; Region Attribute
```

Disable a region before writing new region settings to the MPU if you have previously enabled the region being changed. For example:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER      ; 0xE000ED98, MPU region number register
```

```
STR R1, [R0, #0x0]      ; Region Number
BIC R2, R2, #1          ; Disable
STRH R2, [R0, #0x8]     ; Region Size and Enable
STR R4, [R0, #0x4]      ; Region Base Address
STRH R3, [R0, #0xA]     ; Region Attribute
ORR R2, #1              ; Enable
STRH R2, [R0, #0x8]     ; Region Size and Enable
```

Software must use memory barrier instructions:

- Before MPU setup, if there might be outstanding memory transfers, such as buffered writes, that might be affected by the change in MPU settings.
- After MPU setup, if it includes memory transfers that must use the new MPU settings.

However, memory barrier instructions are not required if the MPU setup process starts by entering an exception handler, or is followed by an exception return, because the exception entry and exception return mechanism cause memory barrier behavior.

Software does not need any memory barrier instructions during MPU setup, because it accesses the MPU through the Private Peripheral Bus (PPB), which is a Strongly Ordered memory region.

For example, if all of the memory access behavior is intended to take effect immediately after the programming sequence, then a DSB instruction and an ISB instruction should be used. A DSB is required after changing MPU settings, such as at the end of context switch. An ISB is required if the code that programs the MPU region or regions is entered using a branch or call. If the programming sequence is entered using a return from exception, or by taking an exception, then an ISB is not required.

#### **Updating an MPU Region Using Multi-Word Writes**

The MPU can be programmed directly using multi-word writes, depending how the information is divided. Consider the following reprogramming:

```
; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0] ; Region Number
STR R2, [R0, #0x4] ; Region Base Address
STR R3, [R0, #0x8] ; Region Attribute, Size and Enable
```

An STM instruction can be used to optimize this:

```
; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STM R0, {R1-R3}    ; Region number, address, attribute, size and enable
```

This operation can be done in two words for pre-packed information, meaning that the **MPU Region Base Address (MPUBASE)** register (see page 191) contains the required region number and has the VALID bit set. This method can be used when the data is statically packed, for example in a boot loader:

```

; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPUBASE      ; 0xE000ED9C, MPU Region Base register
STR R1, [R0, #0x0]    ; Region base address and region number combined
                        ; with VALID (bit 4) set
STR R2, [R0, #0x4]    ; Region Attribute, Size and Enable

```

### Subregions

Regions of 256 bytes or more are divided into eight equal-sized subregions. Set the corresponding bit in the SRD field of the **MPU Region Attribute and Size (MPUATTR)** register (see page 193) to disable a subregion. The least-significant bit of the SRD field controls the first subregion, and the most-significant bit controls the last subregion. Disabling a subregion means another region overlapping the disabled range matches instead. If no other enabled region overlaps the disabled subregion, the MPU issues a fault.

Regions of 32, 64, and 128 bytes do not support subregions. With regions of these sizes, the SRD field must be configured to 0x00, otherwise the MPU behavior is unpredictable.

### Example of SRD Use

Two regions with the same base address overlap. Region one is 128 KB, and region two is 512 KB. To ensure the attributes from region one apply to the first 128 KB region, configure the SRD field for region two to 0x03 to disable the first two subregions, as Figure 3-1 on page 129 shows.

**Figure 3-1. SRD Use Example**

### 3.1.4.2 MPU Access Permission Attributes

The access permission bits, TEX, S, C, B, AP, and XN of the **MPUATTR** register, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

Table 3-3 on page 129 shows the encodings for the TEX, C, B, and S access permission bits. All encodings are shown for completeness, however the current implementation of the Cortex-M4 does not support the concept of cacheability or shareability. Refer to the section called “MPU Configuration for a Stellaris Microcontroller” on page 131 for information on programming the MPU for Stellaris implementations.

**Table 3-3. TEX, S, C, and B Bit Field Encoding**

| TEX  | S              | C | B | Memory Type      | Shareability | Other Attributes |
|------|----------------|---|---|------------------|--------------|------------------|
| 000b | x <sup>a</sup> | 0 | 0 | Strongly Ordered | Shareable    | -                |
| 000  | x <sup>a</sup> | 0 | 1 | Device           | Shareable    | -                |

Table 3-3. TEX, S, C, and B Bit Field Encoding (*continued*)

| TEX | S              | C | B              | Memory Type       | Shareability  | Other Attributes                                                                                            |
|-----|----------------|---|----------------|-------------------|---------------|-------------------------------------------------------------------------------------------------------------|
| 000 | 0              | 1 | 0              | Normal            | Not shareable | Outer and inner write-through. No write allocate.                                                           |
| 000 | 1              | 1 | 0              | Normal            | Shareable     |                                                                                                             |
| 000 | 0              | 1 | 1              | Normal            | Not shareable |                                                                                                             |
| 000 | 1              | 1 | 1              | Normal            | Shareable     |                                                                                                             |
| 001 | 0              | 0 | 0              | Normal            | Not shareable | Outer and inner noncacheable.                                                                               |
| 001 | 1              | 0 | 0              | Normal            | Shareable     |                                                                                                             |
| 001 | x <sup>a</sup> | 0 | 1              | Reserved encoding | -             | -                                                                                                           |
| 001 | x <sup>a</sup> | 1 | 0              | Reserved encoding | -             | -                                                                                                           |
| 001 | 0              | 1 | 1              | Normal            | Not shareable | Outer and inner write-back. Write and read allocate.                                                        |
| 001 | 1              | 1 | 1              | Normal            | Shareable     |                                                                                                             |
| 010 | x <sup>a</sup> | 0 | 0              | Device            | Not shareable | Nonshared Device.                                                                                           |
| 010 | x <sup>a</sup> | 0 | 1              | Reserved encoding | -             | -                                                                                                           |
| 010 | x <sup>a</sup> | 1 | x <sup>a</sup> | Reserved encoding | -             | -                                                                                                           |
| 1BB | 0              | A | A              | Normal            | Not shareable | Cached memory (BB = outer policy, AA = inner policy). See Table 3-4 for the encoding of the AA and BB bits. |
| 1BB | 1              | A | A              | Normal            | Shareable     |                                                                                                             |

a. The MPU ignores the value of this bit.

Table 3-4 on page 130 shows the cache policy for memory attribute encodings with a TEX value in the range of 0x4-0x7.

Table 3-4. Cache Policy for Memory Attribute Encoding

| Encoding, AA or BB | Corresponding Cache Policy          |
|--------------------|-------------------------------------|
| 00                 | Non-cacheable                       |
| 01                 | Write back, write and read allocate |
| 10                 | Write through, no write allocate    |
| 11                 | Write back, no write allocate       |

Table 3-5 on page 130 shows the AP encodings in the **MPUATTR** register that define the access permissions for privileged and unprivileged software.

Table 3-5. AP Bit Field Encoding

| AP Bit Field | Privileged Permissions | Unprivileged Permissions | Description                                                  |
|--------------|------------------------|--------------------------|--------------------------------------------------------------|
| 000          | No access              | No access                | All accesses generate a permission fault.                    |
| 001          | R/W                    | No access                | Access from privileged software only.                        |
| 010          | R/W                    | RO                       | Writes by unprivileged software generate a permission fault. |
| 011          | R/W                    | R/W                      | Full access.                                                 |
| 100          | Unpredictable          | Unpredictable            | Reserved.                                                    |
| 101          | RO                     | No access                | Reads by privileged software only.                           |

**Table 3-5. AP Bit Field Encoding (continued)**

| AP Bit Field | Privileged Permissions | Unprivileged Permissions | Description                                        |
|--------------|------------------------|--------------------------|----------------------------------------------------|
| 110          | RO                     | RO                       | Read-only, by privileged or unprivileged software. |
| 111          | RO                     | RO                       | Read-only, by privileged or unprivileged software. |

**MPU Configuration for a Stellaris Microcontroller**

Stellaris microcontrollers have only a single processor and no caches. As a result, the MPU should be programmed as shown in Table 3-6 on page 131.

**Table 3-6. Memory Region Attributes for Stellaris Microcontrollers**

| Memory Region | TEX  | S | C | B | Memory Type and Attributes                           |
|---------------|------|---|---|---|------------------------------------------------------|
| Flash memory  | 000b | 0 | 1 | 0 | Normal memory, non-shareable, write-through          |
| Internal SRAM | 000b | 1 | 1 | 0 | Normal memory, shareable, write-through              |
| External SRAM | 000b | 1 | 1 | 1 | Normal memory, shareable, write-back, write-allocate |
| Peripherals   | 000b | 1 | 0 | 1 | Device memory, shareable                             |

In current Stellaris microcontroller implementations, the shareability and cache policy attributes do not affect the system behavior. However, using these settings for the MPU regions can make the application code more portable. The values given are for typical situations.

**3.1.4.3 MPU Mismatch**

When an access violates the MPU permissions, the processor generates a memory management fault (see “Exceptions and Interrupts” on page 93 for more information). The **MFAULTSTAT** register indicates the cause of the fault. See page 178 for more information.

**3.1.5 Floating-Point Unit (FPU)**

This section describes the Floating-Point Unit (FPU) and the registers it uses. The FPU provides:

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined Multiply and Accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

The Cortex-M4F FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions. The FPU provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as the IEEE 754 standard. The FPU's single-precision extension registers can also be accessed as 16 doubleword registers for load, store, and move operations.

### 3.1.5.1 FPU Views of the Register Bank

The FPU provides an extension register file containing 32 single-precision registers. These can be viewed as:

- Sixteen 64-bit doubleword registers, D0-D15
- Thirty-two 32-bit single-word registers, S0-S31
- A combination of registers from the above views

**Figure 3-2. FPU Register Bank**

The mapping between the registers is as follows:

- $S\langle 2n \rangle$  maps to the least significant half of  $D\langle n \rangle$
- $S\langle 2n+1 \rangle$  maps to the most significant half of  $D\langle n \rangle$

For example, you can access the least significant half of the value in D6 by accessing S12, and the most significant half of the elements by accessing S13.

### 3.1.5.2 Modes of Operation

The FPU provides three modes of operation to accommodate a variety of applications.

**Full-Compliance mode.** In Full-Compliance mode, the FPU processes all operations according to the IEEE 754 standard in hardware.

**Flush-to-Zero mode.** Setting the FZ bit of the **Floating-Point Status and Control (FPSC)** register enables Flush-to-Zero mode. In this mode, the FPU treats all subnormal input operands of arithmetic CDP operations as zeros in the operation. Exceptions that result from a zero operand are signalled appropriately. VABS, VNEG, and VMOV are not considered arithmetic CDP operations and are not affected by Flush-to-Zero mode. A result that is tiny, as described in the IEEE 754 standard, where the destination precision is smaller in magnitude than the minimum normal value before rounding, is replaced with a zero. The IDC bit in **FPSC** indicates when an input flush occurs. The UFC bit in **FPSC** indicates when a result flush occurs.

**Default NaN mode.** Setting the DN bit in the **FPSC** register enables default NaN mode. In this mode, the result of any arithmetic data processing operation that involves an input NaN, or that generates a NaN result, returns the default NaN. Propagation of the fraction bits is maintained only by VABS,

VNEG, and VMOV operations. All other CDP operations ignore any information in the fraction bits of an input NaN.

### 3.1.5.3 Compliance with the IEEE 754 standard

When Default NaN (DN) and Flush-to-Zero (FZ) modes are disabled, FPv4 functionality is compliant with the IEEE 754 standard in hardware. No support code is required to achieve this compliance.

### 3.1.5.4 Complete Implementation of the IEEE 754 standard

The Cortex-M4F floating point instruction set does not support all operations defined in the IEEE 754-2008 standard. Unsupported operations include, but are not limited to the following:

- Remainder
- Round floating-point number to integer-valued floating-point number
- Binary-to-decimal conversions
- Decimal-to-binary conversions
- Direct comparison of single-precision and double-precision values

The Cortex-M4 FPU supports fused MAC operations as described in the IEEE standard. For complete implementation of the IEEE 754-2008 standard, floating-point functionality must be augmented with library functions.

### 3.1.5.5 IEEE 754 standard implementation choices

#### **NaN handling**

All single-precision values with the maximum exponent field value and a nonzero fraction field are valid NaNs. A most-significant fraction bit of zero indicates a Signaling NaN (SNaN). A one indicates a Quiet NaN (QNaN). Two NaN values are treated as different NaNs if they differ in any bit. The below table shows the default NaN values.

| Sign | Fraction | Fraction                                |
|------|----------|-----------------------------------------|
| 0    | 0xFF     | bit [22] = 1, bits [21:0] are all zeros |

Processing of input NaNs for ARM floating-point functionality and libraries is defined as follows:

- In full-compliance mode, NaNs are handled as described in the ARM Architecture Reference Manual. The hardware processes the NaNs directly for arithmetic CDP instructions. For data transfer operations, NaNs are transferred without raising the Invalid Operation exception. For the non-arithmetic CDP instructions, VABS, VNEG, and VMOV, NaNs are copied, with a change of sign if specified in the instructions, without causing the Invalid Operation exception.
- In default NaN mode, arithmetic CDP instructions involving NaN operands return the default NaN regardless of the fractions of any NaN operands. SNaNs in an arithmetic CDP operation set the IOC flag, FPSCR[0]. NaN handling by data transfer and non-arithmetic CDP instructions is the same as in full-compliance mode.

**Table 3-7. QNaN and SNaN Handling**

| Instruction Type   | Default NaN Mode | With QNaN Operand                                                                                                                                   | With SNaN Operand                                                                                                                       |
|--------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Arithmetic CDP     | Off              | The QNaN or one of the QNaN operands, if there is more than one, is returned according to the rules given in the ARM Architecture Reference Manual. | IOC <sup>a</sup> set. The SNaN is quieted and the result NaN is determined by the rules given in the ARM Architecture Reference Manual. |
|                    | On               | Default NaN returns.                                                                                                                                | IOCa set. Default NaN returns.                                                                                                          |
| Non-arithmetic CDP | Off/On           | NaN passes to destination with sign changed as appropriate.                                                                                         |                                                                                                                                         |
| FCMP(Z)            | -                | Unordered compare.                                                                                                                                  | IOC set. Unordered compare.                                                                                                             |
| FCMPE(Z)           | -                | IOC set. Unordered compare.                                                                                                                         | IOC set. Unordered compare.                                                                                                             |
| Load/store         | Off/On           | All NaNs transferred.                                                                                                                               |                                                                                                                                         |

a. IOC is the Invalid Operation exception flag, FPSCR[0].

### Comparisons

Comparison results modify the flags in the FPSCR. You can use the MVRSPSR\_nzcv instruction (formerly FMSTAT) to transfer the current flags from the FPSCR to the APSR. See the ARM Architecture Reference Manual for mapping of IEEE 754-2008 standard predicates to ARM conditions. The flags used are chosen so that subsequent conditional execution of ARM instructions can test the predicates defined in the IEEE standard.

### Underflow

The Cortex-M4F FPU uses the before rounding form of tininess and the inexact result form of loss of accuracy as described in the IEEE 754-2008 standard to generate Underflow exceptions.

In flush-to-zero mode, results that are tiny before rounding, as described in the IEEE standard, are flushed to a zero, and the UFC flag, FPSCR[3], is set. See the ARM Architecture Reference Manual for information on flush-to-zero mode.

When the FPU is not in flush-to-zero mode, operations are performed on subnormal operands. If the operation does not produce a tiny result, it returns the computed result, and the UFC flag, FPSCR[3], is not set. The IXC flag, FPSCR[4], is set if the operation is inexact. If the operation produces a tiny result, the result is a subnormal or zero value, and the UFC flag, FPSCR[3], is set if the result was also inexact.

#### 3.1.5.6 Exceptions

The FPU sets the cumulative exception status flag in the FPSCR register as required for each instruction, in accordance with the FPUv4 architecture. The FPU does not support user-mode traps. The exception enable bits in the FPSCR read-as-zero, and writes are ignored. The processor also has six output pins, FPIX, FPUFC, FPOFC, FPDZC, FPIDC, and FPIOC, that each reflect the status of one of the cumulative exception flags. For a description of these outputs, see the *ARM Cortex-M4 Integration and Implementation Manual* (ARM DII 0239, available from ARM).

The processor can reduce the exception latency by using lazy stacking. See Auxiliary Control Register, ACTLR on page 4-5. This means that the processor reserves space on the stack for the FP state, but does not save that state information to the stack. See the ARMv7-M Architecture Reference Manual (available from ARM) for more information.

#### 3.1.5.7 Enabling the FPU

The FPU is disabled from reset. You must enable it before you can use any floating-point instructions. The processor must be in privileged mode to read from and write to the **Coprocessor Access**

**Control (CPAC)** register. The below example code sequence enables the FPU in both privileged and user modes.

```
; CPACR is located at address 0xE000ED88
LDR.W R0, =0xE000ED88
; Read CPACR
LDR R1, [R0]
; Set bits 20-23 to enable CP10 and CP11 coprocessors
ORR R1, R1, #(0xF << 20)
; Write back the modified value to the CPACR
STR R1, [R0]; wait for store to complete
DSB
;reset pipeline now the FPU is enabled
ISB
```

## 3.2 Register Map

Table 3-8 on page 135 lists the Cortex-M4 Peripheral SysTick, NVIC, MPU, FPU and SCB registers. The offset listed is a hexadecimal increment to the register's address, relative to the Core Peripherals base address of 0xE000.E000.

**Note:** Register spaces that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

**Table 3-8. Peripherals Register Map**

| Offset                                                       | Name      | Type | Reset       | Description                         | See page |
|--------------------------------------------------------------|-----------|------|-------------|-------------------------------------|----------|
| <b>System Timer (SysTick) Registers</b>                      |           |      |             |                                     |          |
| 0x010                                                        | STCTRL    | R/W  | 0x0000.0004 | SysTick Control and Status Register | 139      |
| 0x014                                                        | STRELOAD  | R/W  | -           | SysTick Reload Value Register       | 141      |
| 0x018                                                        | STCURRENT | R/WC | -           | SysTick Current Value Register      | 142      |
| <b>Nested Vectored Interrupt Controller (NVIC) Registers</b> |           |      |             |                                     |          |
| 0x100                                                        | EN0       | R/W  | 0x0000.0000 | Interrupt 0-31 Set Enable           | 143      |
| 0x104                                                        | EN1       | R/W  | 0x0000.0000 | Interrupt 32-63 Set Enable          | 143      |
| 0x108                                                        | EN2       | R/W  | 0x0000.0000 | Interrupt 64-95 Set Enable          | 143      |
| 0x10C                                                        | EN3       | R/W  | 0x0000.0000 | Interrupt 96-127 Set Enable         | 143      |
| 0x110                                                        | EN4       | R/W  | 0x0000.0000 | Interrupt 128-138 Set Enable        | 144      |
| 0x180                                                        | DIS0      | R/W  | 0x0000.0000 | Interrupt 0-31 Clear Enable         | 145      |
| 0x184                                                        | DIS1      | R/W  | 0x0000.0000 | Interrupt 32-63 Clear Enable        | 145      |
| 0x188                                                        | DIS2      | R/W  | 0x0000.0000 | Interrupt 64-95 Clear Enable        | 145      |
| 0x18C                                                        | DIS3      | R/W  | 0x0000.0000 | Interrupt 96-127 Clear Enable       | 145      |
| 0x190                                                        | DIS4      | R/W  | 0x0000.0000 | Interrupt 128-138 Clear Enable      | 146      |
| 0x200                                                        | PEND0     | R/W  | 0x0000.0000 | Interrupt 0-31 Set Pending          | 147      |
| 0x204                                                        | PEND1     | R/W  | 0x0000.0000 | Interrupt 32-63 Set Pending         | 147      |

Table 3-8. Peripherals Register Map (*continued*)

| Offset | Name    | Type | Reset       | Description                     | See page |

### 3.3 System Timer (SysTick) Register Descriptions

This section lists and describes the System Timer registers, in numerical order by address offset.

**Register 1: SysTick Control and Status Register (STCTRL), offset 0x010****Note:** This register can only be accessed from privileged mode.The SysTick **STCTRL** register enables the SysTick features.

## SysTick Control and Status Register (STCTRL)

Base 0xE000.E000

Offset 0x010

Type R/W, reset 0x0000.0004

|       | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18      | 17    | 16     |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|----|---------|-------|--------|

|           |        |      |       | 0                | The counter is disabled.                                                                                                                                                                                                                                                        |
|           |        |      |       | 1                | Enables SysTick to operate in a multi-shot way. That is, the counter loads the RELOAD value and begins counting down. On reaching 0, the COUNT bit is set and an interrupt is generated if enabled by INTEN. The counter then loads the RELOAD value again and begins counting. |

**Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014**

**Note:** This register can only be accessed from privileged mode.

The **STRELOAD** register specifies the start value to load into the **SysTick Current Value (STCURRENT)** register when the counter reaches 0. The start value can be between 0x1 and 0x00FF.FFFF. A start value of 0 is possible but has no effect because the SysTick interrupt and the COUNT bit are activated when counting from 1 to 0.

SysTick can be configured as a multi-shot timer, repeated over and over, firing every N+1 clock pulses, where N is any value from 1 to 0x00FF.FFFF. For example, if a tick interrupt is required every 100 clock pulses, 99 must be written into the RELOAD field.

Note that in order to access this register correctly, the system clock must be faster than 8 MHz.

**SysTick Reload Value Register (STRELOAD)**

Clearing this register also clears the COUNT bit of the <b>STCTRL</b> register. |

## 3.4 NVIC Register Descriptions

This section lists and describes the NVIC registers, in numerical order by address offset.

The NVIC registers can only be fully accessed from privileged mode, but interrupts can be pended while in unprivileged mode by enabling the **Configuration and Control (CFGCTRL)** register. Any other unprivileged mode access causes a bus fault.

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers.

An interrupt can enter the pending state even if it is disabled.

Before programming the **VTABLE** register to relocate the vector table, ensure the vector table entries of the new vector table are set up for fault handlers, NMI, and all enabled exceptions such as interrupts. For more information, see page 164.

**Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100****Register 5: Interrupt 32-63 Set Enable (EN1), offset 0x104****Register 6: Interrupt 64-95 Set Enable (EN2), offset 0x108****Register 7: Interrupt 96-127 Set Enable (EN3), offset 0x10C**

**Note:** This register can only be accessed from privileged mode.

The **ENn** registers enable interrupts and show which interrupts are enabled. Bit 0 of **EN0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **EN1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **EN2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **EN3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **EN4** (see page 144) corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138.

See Table 2-9 on page 105 for interrupt assignments.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

|---|-----------------------------------------------------------------------------------|
| 0 | On a read, indicates that the interrupt is not pending.<br>On a write, no effect. |
|---|-----------------------------------------------------------------------------------|

|   |                                                                                                                                          |
|---|------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | On a read, indicates that the interrupt is pending.<br>On a write, the corresponding interrupt is set to pending even if it is disabled. |
|---|------------------------------------------------------------------------------------------------------------------------------------------|

If the corresponding interrupt is already pending, setting a bit has no effect.

A bit can only be cleared by setting the corresponding INT[n] bit in the **UNPEND0** register.

**Register 18: Interrupt 128-138 Set Pending (PEND4), offset 0x210**

**Note:** This register can only be accessed from privileged mode.

The **PEND4** register forces interrupts into the pending state and shows which interrupts are pending. Bit 0 corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138. See Table 2-9 on page 105 for interrupt assignments.

|           | A bit can only be cleared by setting the corresponding INT[n] bit in the <b>UNPEND4</b> register. |                                                                                                                                          |            |                                                                                                                                                                                               |

**Register 19: Interrupt 0-31 Clear Pending (UNPEND0), offset 0x280**

**Register 20: Interrupt 32-63 Clear Pending (UNPEND1), offset 0x284**

**Register 21: Interrupt 64-95 Clear Pending (UNPEND2), offset 0x288**

**Register 22: Interrupt 96-127 Clear Pending (UNPEND3), offset 0x28C**

**Note:** This register can only be accessed from privileged mode.

The **UNPENDn** registers show which interrupts are pending and remove the pending state from interrupts. Bit 0 of **UNPEND0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **UNPEND1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **UNPEND2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **UNPEND3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **UNPEND4** (see page 150) corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138.

See Table 2-9 on page 105 for interrupt assignments.

| 0 | On a read, indicates that the interrupt is not pending.<br>On a write, no effect.                                                                                                                                                                                  |
| 1 | On a read, indicates that the interrupt is pending.<br>On a write, clears the corresponding INT[n] bit in the <b>PEND4</b> register, so that interrupt [n] is no longer pending.<br>Setting a bit does not affect the active state of the corresponding interrupt. |

**Register 24: Interrupt 0-31 Active Bit (ACTIVE0), offset 0x300**

**Register 25: Interrupt 32-63 Active Bit (ACTIVE1), offset 0x304**

**Register 26: Interrupt 64-95 Active Bit (ACTIVE2), offset 0x308**

**Register 27: Interrupt 96-127 Active Bit (ACTIVE3), offset 0x30C**

**Note:** This register can only be accessed from privileged mode.

The **UNPENDn** registers indicate which interrupts are active. Bit 0 of **ACTIVE0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **ACTIVE1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **ACTIVE2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **ACTIVE3** corresponds to Interrupt 96; bit 31 corresponds to Interrupt 127. Bit 0 of **ACTIVE4** (see page 152) corresponds to Interrupt 128; bit 10 corresponds to Interrupt 138.

See Table 2-9 on page 105 for interrupt assignments.

**Caution – Do not manually set or clear the bits in this register.**

|           | 1        | The corresponding interrupt is active, or active and pending. |            |                                                                                                                                                                                               |

**Register 29: Interrupt 0-3 Priority (PRI0), offset 0x400**

**Register 30: Interrupt 4-7 Priority (PRI1), offset 0x404**

**Register 31: Interrupt 8-11 Priority (PRI2), offset 0x408**

**Register 32: Interrupt 12-15 Priority (PRI3), offset 0x40C**

**Register 33: Interrupt 16-19 Priority (PRI4), offset 0x410**

**Register 34: Interrupt 20-23 Priority (PRI5), offset 0x414**

**Register 35: Interrupt 24-27 Priority (PRI6), offset 0x418**

**Register 36: Interrupt 28-31 Priority (PRI7), offset 0x41C**

**Register 37: Interrupt 32-35 Priority (PRI8), offset 0x420**

**Register 38: Interrupt 36-39 Priority (PRI9), offset 0x424**

**Register 39: Interrupt 40-43 Priority (PRI10), offset 0x428**

**Register 40: Interrupt 44-47 Priority (PRI11), offset 0x42C**

**Register 41: Interrupt 48-51 Priority (PRI12), offset 0x430**

**Register 42: Interrupt 52-55 Priority (PRI13), offset 0x434**

**Register 43: Interrupt 56-59 Priority (PRI14), offset 0x438**

**Register 44: Interrupt 60-63 Priority (PRI15), offset 0x43C**

**Note:** This register can only be accessed from privileged mode.

The **PRIn** registers (see also page 155) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

| PRIn Register Bit Field | Interrupt        |
|-------------------------|------------------|
| Bits 31:29              | Interrupt [4n+3] |
| Bits 23:21              | Interrupt [4n+2] |
| Bits 15:13              | Interrupt [4n+1] |
| Bits 7:5                | Interrupt [4n]   |

See Table 2-9 on page 105 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRIGROUP** field in the **Application Interrupt and Reset Control (APINT)** register (see page 165) indicates the position of the binary point that splits the priority and subpriority fields.

These registers can only be accessed from privileged mode.

**Register 48: Interrupt 76-79 Priority (PRI19), offset 0x44C**  
**Register 49: Interrupt 80-83 Priority (PRI20), offset 0x450**  
**Register 50: Interrupt 84-87 Priority (PRI21), offset 0x454**  
**Register 51: Interrupt 88-91 Priority (PRI22), offset 0x458**  
**Register 52: Interrupt 92-95 Priority (PRI23), offset 0x45C**  
**Register 53: Interrupt 96-99 Priority (PRI24), offset 0x460**  
**Register 54: Interrupt 100-103 Priority (PRI25), offset 0x464**  
**Register 55: Interrupt 104-107 Priority (PRI26), offset 0x468**  
**Register 56: Interrupt 108-111 Priority (PRI27), offset 0x46C**  
**Register 57: Interrupt 112-115 Priority (PRI28), offset 0x470**  
**Register 58: Interrupt 116-119 Priority (PRI29), offset 0x474**  
**Register 59: Interrupt 120-123 Priority (PRI30), offset 0x478**  
**Register 60: Interrupt 124-127 Priority (PRI31), offset 0x47C**  
**Register 61: Interrupt 128-131 Priority (PRI32), offset 0x480**  
**Register 62: Interrupt 132-135 Priority (PRI33), offset 0x484**  
**Register 63: Interrupt 136-138 Priority (PRI34), offset 0x488**

**Note:** This register can only be accessed from privileged mode.

The **PRIn** registers (see also page 153) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

| PRIn Register Bit Field | Interrupt        |
|-------------------------|------------------|
| Bits 31:29              | Interrupt [4n+3] |
| Bits 23:21              | Interrupt [4n+2] |
| Bits 15:13              | Interrupt [4n+1] |
| Bits 7:5                | Interrupt [4n]   |

See Table 2-9 on page 105 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRIGROUP** field in the **Application Interrupt and Reset Control (APINT)** register (see page 165) indicates the position of the binary point that splits the priority and subpriority fields.

These registers can only be accessed from privileged mode.

## Register 64: Software Trigger Interrupt (SWTRIG), offset 0xF00

**Note:** Only privileged software can enable unprivileged access to the **SWTRIG** register.

Writing an interrupt number to the **SWTRIG** register generates a Software Generated Interrupt (SGI). See Table 2-9 on page 105 for interrupt assignments.

When the MAINPEND bit in the **Configuration and Control (CFGCTRL)** register (see page 169) is set, unprivileged software can access the **SWTRIG** register.

## 3.5 System Control Block (SCB) Register Descriptions

This section lists and describes the System Control Block (SCB) registers, in numerical order by address offset. The SCB registers can only be accessed from privileged mode.

All registers must be accessed with aligned word accesses except for the **FAULTSTAT** and **SYSPRI1-SYSPRI3** registers, which can be accessed with byte or aligned halfword or word accesses. The processor does not support unaligned accesses to system control block registers.

**Register 65: Auxiliary Control (ACTLR), offset 0x008**

**Note:** This register can only be accessed from privileged mode.

The **ACTLR** register provides disable bits for IT folding, write buffer use for accesses to the default memory map, and interruption of multi-cycle instructions. By default, this register is set to provide optimum performance from the Cortex-M4 processor and does not normally require modification.

In some situations, the processor can start executing the first instruction in an IT block while it is still executing the IT instruction. This behavior is called *IT folding*, and improves performance. However, IT folding can cause jitter in looping. If a task must avoid jitter, set the DISFOLD bit before executing the task, to disable IT folding.

**Register 67: Interrupt Control and State (INTCTRL), offset 0xD04**

**Note:** This register can only be accessed from privileged mode.

The **INCTRL** register provides a set-pending bit for the NMI exception, and set-pending and clear-pending bits for the PendSV and SysTick exceptions. In addition, bits in this register indicate the exception number of the exception being processed, whether there are preempted active exceptions, the exception number of the highest priority pending exception, and whether any interrupts are pending.

When writing to **INCTRL**, the effect is unpredictable when writing a 1 to both the PENDSV and UNPENDSV bits, or writing a 1 to both the PENDSTSET and PENDSTCLR bits.

**Interrupt Control and State (INTCTRL)**

Base 0xE000.E000

Offset 0xD04

Type R/W, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|-------------|
|-----------|------|------|-------|-------------|

|    |         |     |   |                 |
|----|---------|-----|---|-----------------|
| 31 | NMISSET | R/W | 0 | NMI Set Pending |
|----|---------|-----|---|-----------------|

**Value Description**

0 On a read, indicates an NMI exception is not pending.

On a write, no effect.

1 On a read, indicates an NMI exception is pending.

On a write, changes the NMI exception state to pending.

Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it registers the setting of this bit, and clears this bit on entering the interrupt handler. A read of this bit by the NMI exception handler returns 1 only if the NMI signal is reasserted while the processor is executing that handler.

|-------|----------|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30:29 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
|-------|----------|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|    |        |     |   |                    |
|----|--------|-----|---|--------------------|
| 28 | PENDSV | R/W | 0 | PendSV Set Pending |
|----|--------|-----|---|--------------------|

**Value Description**

0 On a read, indicates a PendSV exception is not pending.

On a write, no effect.

1 On a read, indicates a PendSV exception is pending.

On a write, changes the PendSV exception state to pending.

Setting this bit is the only way to set the PendSV exception state to pending. This bit is cleared by writing a 1 to the UNPENDSV bit.

## Register 69: Application Interrupt and Reset Control (APINT), offset 0xD0C

**Note:** This register can only be accessed from privileged mode.

The **APINT** register provides priority grouping control for the exception model, endian status for data accesses, and reset control of the system. To write to this register, 0x05FA must be written to the VECTKEY field, otherwise the write is ignored.

The PRIGROUP field indicates the position of the binary point that splits the INTx fields in the **Interrupt Priority (PRIx)** registers into separate group priority and subpriority fields. Table 3-9 on page 165 shows how the PRIGROUP value controls this split. The bit numbers in the Group Priority Field and Subpriority Field columns in the table refer to the bits in the INTA field. For the INTB field, the corresponding bits are 15:13; for INTC, 23:21; and for INTD, 31:29.

**Note:** Determining preemption of an exception uses only the group priority field.

**Table 3-9. Interrupt Priority Levels**

| PRIGROUP Bit Field | Binary Point <sup>a</sup> | Group Priority Field | Subpriority Field | Group Priorities | Subpriorities |
|--------------------|---------------------------|----------------------|-------------------|------------------|---------------|
| 0x0 - 0x4          | bxxx.                     | [7:5]                | None              | 8                | 1             |
| 0x5                | bxx.y                     | [7:6]                | [5]               | 4                | 2             |
| 0x6                | bx.yy                     | [7]                  | [6:5]             | 2                | 4             |
| 0x7                | b.yyy                     | None                 | [7:5]             | 1                | 8             |

a. INTx field showing the binary point. An x denotes a group priority field bit, and a y denotes a subpriority field bit.

**Register 71: Configuration and Control (CFGCTRL), offset 0xD14**

**Note:** This register can only be accessed from privileged mode.

The **CFGCTRL** register controls entry to Thread mode and enables: the handlers for NMI, hard fault and faults escalated by the **FAULTMASK** register to ignore bus faults; trapping of divide by zero and unaligned accesses; and access to the **SWTRIG** register by unprivileged software (see page 157).

**Configuration and Control (CFGCTRL)**

**Register 72: System Handler Priority 1 (SYSPRI1), offset 0xD18**

**Note:** This register can only be accessed from privileged mode.

The **SYSPRI1** register configures the priority level, 0 to 7 of the usage fault, bus fault, and memory management fault exception handlers. This register is byte-accessible.

**System Handler Priority 1 (SYSPRI1)**

Base 0xE000.E000

Offset 0xD18

Type R/W, reset 0x0000.0000

**Register 75: System Handler Control and State (SYSHNDCTRL), offset 0xD24**

**Note:** This register can only be accessed from privileged mode.

The **SYSHNDCTRL** register enables the system handlers, and indicates the pending status of the usage fault, bus fault, memory management fault, and SVC exceptions as well as the active status of the system handlers.

If a system handler is disabled and the corresponding fault occurs, the processor treats the fault as a hard fault.

This register can be modified to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

**Caution – Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.**

**If the value of a bit in this register must be modified after enabling the system handlers, a read-modify-write procedure must be used to ensure that only the required bit is modified.**

|           |      |      |       | 0 Memory management fault is not active.                                                                                                               |
|           |      |      |       | 1 Memory management fault is active.                                                                                                                   |
|           |      |      |       | This bit can be modified to change the active status of the memory management fault exception, however, see the Caution above before setting this bit. |

**Register 76: Configurable Fault Status (FAULTSTAT), offset 0xD28**

**Note:** This register can only be accessed from privileged mode.

The **FAULTSTAT** register indicates the cause of a memory management fault, bus fault, or usage fault. Each of these functions is assigned to a subregister as follows:

- **Usage Fault Status (UFAULTSTAT)**, bits 31:16
- **Bus Fault Status (BFAULTSTAT)**, bits 15:8
- **Memory Management Fault Status (MFAULTSTAT)**, bits 7:0

**FAULTSTAT** is byte accessible. **FAULTSTAT** or its subregisters can be accessed as follows:

- The complete **FAULTSTAT** register, with a word access to offset 0xD28
- The **MFAULTSTAT**, with a byte access to offset 0xD28
- The **MFAULTSTAT** and **BFAULTSTAT**, with a halfword access to offset 0xD28
- The **BFAULTSTAT**, with a byte access to offset 0xD29
- The **UFAULTSTAT**, with a halfword access to offset 0xD2A

Bits are cleared by writing a 1 to them.

In a fault handler, the true faulting address can be determined by:

1. Read and save the **Memory Management Fault Address (MMADDR)** or **Bus Fault Address (FAULTADDR)** value.
2. Read the MMARV bit in **MFAULTSTAT**, or the BFARV bit in **BFAULTSTAT** to determine if the **MMADDR** or **FAULTADDR** contents are valid.

Software must follow this sequence because another higher priority exception might change the **MMADDR** or **FAULTADDR** value. For example, if a higher priority handler preempts the current fault handler, the other fault might change the **MMADDR** or **FAULTADDR** value.

**Configurable Fault Status (FAULTSTAT)**

Base 0xE000.E000

Offset 0xD28

Type R/W1C, reset 0x0000.0000

**Register 77: Hard Fault Status (HFAULTSTAT), offset 0xD2C**

**Note:** This register can only be accessed from privileged mode.

The **HFAULTSTAT** register gives information about events that activate the hard fault handler.

Bits are cleared by writing a 1 to them.

**Hard Fault Status (HFAULTSTAT)**

Base 0xE000.E000

Offset 0xD2C

Type R/W1C, reset 0x0000.0000

**Register 78: Memory Management Fault Address (MMADDR), offset 0xD34**

**Note:** This register can only be accessed from privileged mode.

The **MMADDR** register contains the address of the location that generated a memory management fault. When an unaligned access faults, the address in the **MMADDR** register is the actual address that faulted. Because a single read or write instruction can be split into multiple aligned accesses, the fault address can be any address in the range of the requested access size. Bits in the **Memory Management Fault Status (MFAULTSTAT)** register indicate the cause of the fault and whether the value in the **MMADDR** register is valid (see page 178).

Register 79: Bus Fault Address (FAULTADDR), offset 0xD38

**Note:** This register can only be accessed from privileged mode.

The **FAULTADDR** register contains the address of the location that generated a bus fault. When an unaligned access faults, the address in the **FAULTADDR** register is the one requested by the instruction, even if it is not the address of the fault. Bits in the **Bus Fault Status (BFAULTSTAT)** register indicate the cause of the fault and whether the value in the **FAULTADDR** register is valid (see page 178).

3.6 Memory Protection Unit (MPU) Register Descriptions

This section lists and describes the Memory Protection Unit (MPU) registers, in numerical order by address offset.

The MPU registers can only be accessed from privileged mode.

**Register 80: MPU Type (MPUTYPE), offset 0xD90****Note:** This register can only be accessed from privileged mode.

The **MPUTYPE** register indicates whether the MPU is present, and if so, how many regions it supports.

**Register 81: MPU Control (MPUCTRL), offset 0xD94**

**Note:** This register can only be accessed from privileged mode.

The **MPUCTRL** register enables the MPU, enables the default memory map background region, and enables use of the MPU when in the hard fault, Non-maskable Interrupt (NMI), and **Fault Mask Register (FAULTMASK)** escalated handlers.

When the ENABLE and PRIVDEFEN bits are both set:

- For privileged accesses, the default memory map is as described in “Memory Model” on page 93. Any access by privileged software that does not address an enabled memory region behaves as defined by the default memory map.
- Any access by unprivileged software that does not address an enabled memory region causes a memory management fault.

Execute Never (XN) and Strongly Ordered rules always apply to the System Control Space regardless of the value of the ENABLE bit.

When the ENABLE bit is set, at least one region of the memory map must be enabled for the system to function unless the PRIVDEFEN bit is set. If the PRIVDEFEN bit is set and no regions are enabled, then only privileged software can operate.

When the ENABLE bit is clear, the system uses the default memory map, which has the same memory attributes as if the MPU is not implemented (see Table 2-5 on page 96 for more information). The default memory map applies to accesses from both privileged and unprivileged software.

When the MPU is enabled, accesses to the System Control Space and vector table are always permitted. Other areas are accessible based on regions and whether PRIVDEFEN is set.

Unless HFNMIENA is set, the MPU is not enabled when the processor is executing the handler for an exception with priority –1 or –2. These priorities are only possible when handling a hard fault or NMI exception or when **FAULTMASK** is enabled. Setting the HFNMIENA bit enables the MPU when operating with these two priorities.

**Register 82: MPU Region Number (MPUNUMBER), offset 0xD98**

**Note:** This register can only be accessed from privileged mode.

The **MPUNUMBER** register selects which memory region is referenced by the **MPU Region Base Address (MPUBASE)** and **MPU Region Attribute and Size (MPUATTR)** registers. Normally, the required region number should be written to this register before accessing the **MPUBASE** or the **MPUATTR** register. However, the region number can be changed by writing to the **MPUBASE** register with the VALID bit set (see page 191). This write updates the value of the REGION field.

| 31:3      | reserved | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 2:0       | NUMBER   | R/W  | 0x0        | MPU Region to Access<br>This field indicates the MPU region referenced by the <b>MPUBASE</b> and <b>MPUATTR</b> registers. The MPU supports eight memory regions.                             |

**Register 83: MPU Region Base Address (MPUBASE), offset 0xD9C****Register 84: MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4****Register 85: MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC****Register 86: MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4**

**Note:** This register can only be accessed from privileged mode.

The **MPUBASE** register defines the base address of the MPU region selected by the **MPU Region Number (MPUNUMBER)** register and can update the value of the **MPUNUMBER** register. To change the current region number and update the **MPUNUMBER** register, write the **MPUBASE** register with the **VALID** bit set.

The **ADDR** field is bits 31:*N* of the **MPUBASE** register. Bits (*N*-1):5 are reserved. The region size, as specified by the **SIZE** field in the **MPU Region Attribute and Size (MPUATTR)** register, defines the value of *N* where:

$$N = \text{Log}_2(\text{Region size in bytes})$$

If the region size is configured to 4 GB in the **MPUATTR** register, there is no valid **ADDR** field. In this case, the region occupies the complete memory map, and the base address is 0x0000.0000.

The base address is aligned to the size of the region. For example, a 64-KB region must be aligned on a multiple of 64 KB, for example, at 0x0001.0000 or 0x0002.0000.

**Register 87: MPU Region Attribute and Size (MPUATTR), offset 0xDA0****Register 88: MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8****Register 89: MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0****Register 90: MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8**

**Note:** This register can only be accessed from privileged mode.

The **MPUATTR** register defines the region size and memory attributes of the MPU region specified by the **MPU Region Number (MPUNUMBER)** register and enables that region and any subregions.

The **MPUATTR** register is accessible using word or halfword accesses with the most-significant halfword holding the region attributes and the least-significant halfword holds the region size and the region and subregion enable bits.

The MPU access permission attribute bits, XN, AP, TEX, S, C, and B, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

The **SIZE** field defines the size of the MPU memory region specified by the **MPUNUMBER** register as follows:

$$(\text{Region size in bytes}) = 2^{(\text{SIZE}+1)}$$

The smallest permitted region size is 32 bytes, corresponding to a **SIZE** value of 4. Table 3-10 on page 193 gives example **SIZE** values with the corresponding region size and value of **N** in the **MPU Region Base Address (MPUBASE)** register.

**Table 3-10. Example SIZE Field Values**

| SIZE Encoding | Region Size | Value of N <sup>a</sup>                                                              | Note                   |
|---------------|-------------|--------------------------------------------------------------------------------------|------------------------|
| 00100b (0x4)  | 32 B        | 5                                                                                    | Minimum permitted size |
| 01001b (0x9)  | 1 KB        | 10                                                                                   | -                      |
| 10011b (0x13) | 1 MB        | 20                                                                                   | -                      |
| 11101b (0x1D) | 1 GB        | 30                                                                                   | -                      |
| 11111b (0x1F) | 4 GB        | No valid ADDR field in <b>MPUBASE</b> ; the region occupies the complete memory map. | Maximum possible size  |

a. Refers to the **N** parameter in the **MPUBASE** register (see page 191).

## 3.7 Floating-Point Unit (FPU) Register Descriptions

This section lists and describes the Floating-Point Unit (FPU) registers, in numerical order by address offset.

## Register 91: Coprocessor Access Control (CPAC), offset 0xD88

The **CPAC** register specifies the access privileges for coprocessors.

### Coprocessor Access Control (CPAC)

Base 0xE000.E000

**Register 92: Floating-Point Context Control (FPCC), offset 0xF34**

The **FPCC** register sets or returns FPU control data.

**Floating-Point Context Control (FPCC)**

Base 0xE000.E000

Offset 0xF34

Type R/W, reset 0xC000.0000

## 4 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The Stellaris® JTAG controller works with the ARM JTAG controller built into the Cortex-M4F core by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Stellaris JTAG instructions select the Stellaris TDO output. The multiplexer is controlled by the Stellaris JTAG controller, which has comprehensive programming for the ARM, Stellaris, and unimplemented JTAG instructions.

The Stellaris JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
  - Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
  - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
  - Embedded Trace Macrocell (ETM) for instruction trace capture
  - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

See the *ARM® Debug Interface V5 Architecture Specification* for more information on the ARM JTAG controller.

## 4.1 Block Diagram

Figure 4-1. JTAG Module Block Diagram

## 4.2 Signal Description

The following table lists the external signals of the JTAG/SWD controller and describes the function of each. The JTAG/SWD controller signals are alternate functions for some GPIO signals, however note that the reset state of the pins is for the JTAG/SWD function. The JTAG/SWD controller signals are under commit protection and require a special process to be configured as GPIOs, see “Commit Control” on page 630. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the JTAG/SWD controller signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 644) is set to choose the JTAG/SWD function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPTCL)** register (page 661) to assign the JTAG/SWD controller signals to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 623.

Table 4-1. JTAG\_SWD\_SWO Signals (64LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description         |
|----------|------------|--------------------------|----------|--------------------------|---------------------|
| SWCLK    | 52         | PC0 (1)                  | I        | TTL                      | JTAG/SWD CLK.       |
| SWDIO    | 51         | PC1 (1)                  | I/O      | TTL                      | JTAG TMS and SWDIO. |
| SWO      | 49         | PC3 (1)                  | O        | TTL                      | JTAG TDO and SWO.   |
| TCK      | 52         | PC0 (1)                  | I        | TTL                      | JTAG/SWD CLK.       |
| TDI      | 50         | PC2 (1)                  | I        | TTL                      | JTAG TDI.           |
| TDO      | 49         | PC3 (1)                  | O        | TTL                      | JTAG TDO and SWO.   |

Table 4-1. JTAG\_SWD\_SWO Signals (64LQFP) (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description         |
|----------|------------|--------------------------|----------|--------------------------|---------------------|
| TMS      | 51         | PC1 (1)                  | I        | TTL                      | JTAG TMS and SWDIO. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 4.3 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 4-1 on page 202. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TCK and TMS inputs. The current state of the TAP controller depends on the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TD0, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST and INTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TD0 is always connected (see Table 4-3 on page 209 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 1325 for JTAG timing diagrams.

**Note:** Of all the possible reset sources, only Power-On reset (POR) and the assertion of the RST input have any effect on the JTAG module. The pin configurations are reset by both the RST input and POR, whereas the internal JTAG logic is only reset with POR. See “Reset Sources” on page 214 for more information on reset.

### 4.3.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TD0. These pins and their associated state after a power-on reset or reset caused by the RST input are given in Table 4-2. Detailed information on each pin follows.

**Note:** The following pins are configured as JTAG port pins out of reset. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 623 for information on how to reprogram the configuration of these pins.

Table 4-2. JTAG Port Pins State after Power-On Reset or  $\overline{\text{RST}}$  assertion

| Pin Name | Data Direction | Internal Pull-Up | Internal Pull-Down | Drive Strength | Drive Value |
|----------|----------------|------------------|--------------------|----------------|-------------|
| TCK      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TMS      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TDI      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TD0      | Output         | Enabled          | Disabled           | 2-mA driver    | High-Z      |

#### 4.3.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks and to ensure that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset, assuring that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source (see page 650 and page 652).

#### 4.3.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state may be entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 4-2 on page 205.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost (see page 650).

#### 4.3.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, may present this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost (see page 650).

#### 4.3.1.4 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset, assuring that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and

pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states (see page 650 and page 652).

### 4.3.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 4-2. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). In order to reset the JTAG module after the microcontroller has been powered on, the TMS input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

**Figure 4-2. Test Access Port State Machine**

### 4.3.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows this information to be shifted out on TD0 during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TD0, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 208.

### 4.3.4 Operational Considerations

Certain operational parameters must be considered when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

#### 4.3.4.1 GPIO Functionality

When the microcontroller is reset with either a POR or RST, the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality (DEN[3:0] set in the **Port C GPIO Digital Enable (GPIODEN)** register), enabling the pull-up resistors (PUE[3:0] set in the **Port C GPIO Pull-Up Select (GPIOPUR)** register), disabling the pull-down resistors (PDE[3:0] cleared in the **Port C GPIO Pull-Down Select (GPIOPDR)** register) and enabling the alternate hardware function (AFSEL[3:0] set in the **Port C GPIO Alternate Function Select (GPIOAFSEL)** register) on the JTAG/SWD pins. See page 644, page 650, page 652, and page 655.

It is possible for software to configure these pins as GPIOs after reset by clearing AFSEL[3:0] in the **Port C GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

---

**Caution** – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

---

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins (PC[3:0]) and the NMI pin (PD7 and PF0). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 644), **GPIO Pull Up Select (GPIOPUR)** register (see page 650), **GPIO Pull-Down Select (GPIOPDR)** register (see page 652), and **GPIO Digital Enable (GPIODEN)** register (see page 655) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 657) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 658) have been set.

#### 4.3.4.2 Communication with JTAG/SWD

Because the debug clock and the system clock can be running at different frequencies, care must be taken to maintain reliable communication with the JTAG/SWD interface. In the Capture-DR state, the result of the previous transaction, if any, is returned, together with a 3-bit ACK response. Software should check the ACK response to see if the previous operation has completed before initiating a new transaction. Alternatively, if the system clock is at least 8 times faster than the debug clock (TCK or SWCLK), the previous operation has enough time to complete and the ACK bits do not have to be checked.

#### 4.3.4.3 Recovering a "Locked" Microcontroller

**Note:** Performing the sequence below restores the non-volatile registers discussed in “Non-Volatile Register Programming” on page 508 to their factory default values. The mass erase of the Flash memory caused by the sequence below occurs prior to the non-volatile registers being restored.

In addition, the EEPROM is erased and its wear-leveling counters are returned to factory default values when performing the sequence below.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug port unlock sequence that can be used to recover the microcontroller. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the microcontroller in reset mass erases the Flash memory. The debug port unlock sequence is:

1. Assert and hold the RST signal.
2. Apply power to the device.
3. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence on the section called “JTAG-to-SWD Switching” on page 208.
4. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence on the section called “SWD-to-JTAG Switching” on page 208.
5. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
6. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
7. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
8. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
9. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
10. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
11. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
12. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
13. Release the RST signal.
14. Wait 400 ms.
15. Power-cycle the microcontroller.

#### 4.3.4.4 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M4F core without having to perform, or have any knowledge of, JTAG cycles. This integration is accomplished with a SWD preamble that is issued before the SWD session begins.

The switching preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequence of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Debug Interface V5 Architecture Specification*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This instance is the only one

where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

### **JTAG-to-SWD Switching**

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send the switching preamble to the microcontroller. The 16-bit TMS command for switching to SWD mode is defined as b1110.0111.1001.1110, transmitted LSB first. This command can also be represented as 0xE79E when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit JTAG-to-SWD switch command, 0xE79E, on TMS.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in SWD mode, the SWD goes into the line reset state before sending the switch sequence.

### **SWD-to-JTAG Switching**

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch command to the microcontroller. The 16-bit TMS command for switching to JTAG mode is defined as b1110.0111.0011.1100, transmitted LSB first. This command can also be represented as 0xE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit SWD-to-JTAG switch command, 0xE73C, on TMS.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in JTAG mode, the JTAG goes into the Test Logic Reset state before sending the switch sequence.

## **4.4 Initialization and Configuration**

After a Power-On-Reset or an external reset (RST), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. To return the pins to their JTAG functions, enable the four JTAG pins (PC[3:0]) for their alternate function using the **GPIOAFSEL** register. In addition to enabling the alternate functions, any other changes to the GPIO pad configurations on the four JTAG pins (PC[3:0]) should be returned to their default settings.

## **4.5 Register Descriptions**

The registers in the JTAG TAP Controller or Shift Register chains are not memory mapped and are not accessible through the on-chip Advanced Peripheral Bus (APB). Instead, the registers within the JTAG controller are all accessed serially through the TAP Controller. These registers include the Instruction Register and the six Data Registers.

### 4.5.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain connected between the JTAG TDI and TDO pins with a parallel load register. When the TAP Controller is placed in the correct states, bits can be shifted into the IR. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the IR bits is shown in Table 4-3. A detailed explanation of each instruction, along with its associated Data Register, follows.

**Table 4-3. JTAG Instruction Register Commands**

| IR[3:0]    | Instruction      | Description                                                                                                                        |
|------------|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 0x0        | EXTEST           | Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.                          |
| 0x1        | INTEST           | Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction into the controller.                    |
| 0x2        | SAMPLE / PRELOAD | Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in. |
| 0x8        | ABORT            | Shifts data into the ARM Debug Port Abort Register.                                                                                |
| 0xA        | DPACC            | Shifts data into and out of the ARM DP Access Register.                                                                            |
| 0xB        | APACC            | Shifts data into and out of the ARM AC Access Register.                                                                            |
| 0xE        | IDCODE           | Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.                |
| 0xF        | BYPASS           | Connects TDI to TDO through a single Shift Register chain.                                                                         |
| All Others | Reserved         | Defaults to the BYPASS instruction to ensure that TDI is always connected to TDO.                                                  |

#### 4.5.1.1 EXTEST Instruction

The EXTEST instruction is not associated with its own Data Register chain. Instead, the EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. With tests that drive known values out of the controller, this instruction can be used to verify connectivity. While the EXTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 4.5.1.2 INTEST Instruction

The INTEST instruction is not associated with its own Data Register chain. Instead, the INTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the INTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the inputs are used to drive the signals going into the core rather than the signals coming from the GPIO pads. With tests that drive known values into the controller, this instruction can be used for testing. It is important to note that although the RST input pin is on the Boundary Scan Data Register chain, it is only observable. While the INTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 4.5.1.3 **SAMPLE/PRELOAD Instruction**

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TD0. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out on TD0 while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST and INTEST instructions to drive data into or out of the controller. See “Boundary Scan Data Register” on page 211 for more information.

#### 4.5.1.4 **ABORT Instruction**

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TD0. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. See the “ABORT Data Register” on page 212 for more information.

#### 4.5.1.5 **DPACC Instruction**

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TD0. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. See “DPACC Data Register” on page 212 for more information.

#### 4.5.1.6 **APACC Instruction**

The APACC instruction connects the associated APACC Data Register chain between TDI and TD0. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. See “APACC Data Register” on page 212 for more information.

#### 4.5.1.7 **IDCODE Instruction**

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TD0. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure input and output data streams. IDCODE is the default instruction loaded into the JTAG Instruction Register when a Power-On-Reset (POR) is asserted, or the Test-Logic-Reset state is entered. See “IDCODE Data Register” on page 211 for more information.

#### 4.5.1.8 **BYPASS Instruction**

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TD0. This instruction is used to create a minimum length serial path between the TDI and TD0 ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by

allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. See “BYPASS Data Register” on page 211 for more information.

## 4.5.2 Data Registers

The JTAG module contains six Data Registers. These serial Data Register chains include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT and are discussed in the following sections.

### 4.5.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-3. The standard requires that every JTAG-compliant microcontroller implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x4BA0.0477. This value allows the debuggers to automatically configure themselves to work correctly with the Cortex-M4F during debug.

**Figure 4-3. IDCODE Register Format**

### 4.5.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-4. The standard requires that every JTAG-compliant microcontroller implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

**Figure 4-4. BYPASS Register Format**

### 4.5.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 4-5. Each GPIO pin, starting with a GPIO pin next to the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as shown in the figure.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain

to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST and INTEST instructions. The EXTEST instruction forces data out of the controller, and the INTEST instruction forces data into the controller.

**Figure 4-5. Boundary Scan Register Format**

#### 4.5.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

#### 4.5.2.5 DPACC Data Register

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

#### 4.5.2.6 ABORT Data Register

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

## 5 System Control

System control configures the overall operation of the device and provides information about the device. Configurable features include reset control, NMI operation, power control, clock control, and low-power modes.

### 5.1 Signal Description

The following table lists the external signals of the System Control module and describes the function of each. The NMI signal is the alternate function for two GPIO signals and functions as a GPIO after reset. PD7 and PF0 are under commit protection and require a special process to be configured as any alternate function or to subsequently return to the GPIO function, see “Commit Control” on page 630. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the NMI signal. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 644) should be set to choose the NMI function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 661) to assign the NMI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 623. The remaining signals (with the word “fixed” in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Table 5-1. System Control & Clocks Signals (64LQFP)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                               |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------------------------------------------------------------|
| NMI      | 10<br>28   | PD7 (8)<br>PF0 (8)       | I        | TTL                      | Non-maskable interrupt.                                                                   |
| OSC0     | 40         | fixed                    | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                       |
| OSC1     | 41         | fixed                    | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| RST      | 38         | fixed                    | I        | TTL                      | System reset input.                                                                       |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

### 5.2 Functional Description

The System Control module provides the following capabilities:

- Device identification, see “Device Identification” on page 213
- Local control, such as reset (see “Reset Control” on page 214), power (see “Power Control” on page 219) and clock control (see “Clock Control” on page 220)
- System control (Run, Sleep, and Deep-Sleep modes), see “System Control” on page 227

#### 5.2.1 Device Identification

Several read-only registers provide software with information on the microcontroller, such as version, part number, memory sizes, and peripherals present on the device. The **Device Identification 0 (DID0)** (page 236) and **Device Identification 1 (DID1)** (page 238) registers provide details about the device's version, package, temperature range, and so on. The Peripheral Present registers starting at System Control offset 0x300, such as the **Watchdog Timer Peripheral Present (PPWD)** register, provide information on how many of each type of module are included on the device. Finally,

information about the capabilities of the on-chip peripherals are provided at offset 0xFC0 in each peripheral's register space in the Peripheral Properties registers, such as the **GPTM Peripheral Properties (GPTMPP)** register. Previous generations of Stellaris® devices used the **Device Capabilities (DC0-DC9)** registers for information about the peripherals and their capabilities. These registers are present on this device for backward software capability, but provide no information about peripherals that were not available on older devices.

## 5.2.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

### 5.2.2.1 Reset Sources

The LM4F231H5QR microcontroller has six sources of reset:

1. Power-on reset (POR) (see page 215).
2. External reset input pin (RST) assertion (see page 215).
3. Internal brown-out (BOR) detector (see page 217).
4. Software-initiated reset (with the software reset registers) (see page 217).
5. A watchdog timer reset condition violation (see page 218).
6. MOSC failure (see page 219).

Table 5-2 provides a summary of results of the various reset operations.

**Table 5-2. Reset Sources**

| Reset Source                                                                              | Core Reset? | JTAG Reset?     | On-Chip Peripherals Reset? |
|-------------------------------------------------------------------------------------------|-------------|-----------------|----------------------------|
| Power-On Reset                                                                            | Yes         | Yes             | Yes                        |
| RST                                                                                       | Yes         | Pin Config Only | Yes                        |
| Brown-Out Reset                                                                           | Yes         | Pin Config Only | Yes                        |
| Software System Request<br>Reset using the SYSRESREQ<br>bit in the <b>APINT</b> register. | Yes         | Pin Config Only | Yes                        |
| Software System Request<br>Reset using the VECTRESET<br>bit in the <b>APINT</b> register. | Yes         | Pin Config Only | No                         |
| Software Peripheral Reset                                                                 | No          | Pin Config Only | Yes <sup>a</sup>           |
| Watchdog Reset                                                                            | Yes         | Pin Config Only | Yes                        |
| MOSC Failure Reset                                                                        | Yes         | Pin Config Only | Yes                        |

a. Programmable on a module-by-module basis using the Software Reset Control Registers.

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an internal POR is the cause, in which case, all the bits in the **RESC** register are cleared except for the POR indicator. A bit in the **RESC** register can be cleared by writing a 0.

At any reset that resets the core, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal as configured in the **Boot Configuration (BOOTCFG)** register.

At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the EN bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If then EN bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

For example, if the **BOOTCFG** register is written and committed with the value of 0x0000.3C01, then PB7 is examined at reset to determine if the ROM Boot Loader should be executed. If PB7 is Low, the core unconditionally begins executing the ROM boot loader. If PB7 is High, then the application in Flash memory is executed if the reset vector at location 0x0000.0004 is not 0xFFFF.FFFF. Otherwise, the ROM boot loader is executed.

### 5.2.2.2 Power-On Reset (POR)

**Note:** The JTAG controller can only be reset by the power-on reset.

The internal Power-On Reset (POR) circuit monitors the power supply voltage ( $V_{DD}$ ) and generates a reset signal to all of the internal logic including JTAG when the power supply ramp reaches a threshold value ( $V_{TH}$ ). The microcontroller must be operating within the specified operating parameters when the on-chip power-on reset pulse is complete (see “Power and Brown-Out” on page 1326). For applications that require the use of an external reset signal to hold the microcontroller in reset longer than the internal POR, the RST input may be used as discussed in “External  $\overline{RST}$  Pin” on page 215.

The Power-On Reset sequence is as follows:

1. The microcontroller waits for internal POR to go inactive.
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The internal POR is only active on the initial power-up of the microcontroller. The Power-On Reset timing is shown in Figure 24-6 on page 1327.

### 5.2.2.3 External $\overline{RST}$ Pin

**Note:** It is recommended that the trace for the RST signal must be kept as short as possible. Be sure to place any components connected to the RST signal as close to the microcontroller as possible.

If the application only uses the internal POR circuit, the RST input must be connected to the power supply ( $V_{DD}$ ) through an optional pull-up resistor (0 to 100K  $\Omega$ ) as shown in Figure 5-1 on page 216. The RST input has filtering which requires a minimum pulse width in order for the reset pulse to be recognized, see Table 24-7 on page 1327.

**Figure 5-1. Basic  $\overline{\text{RST}}$  Configuration**

$R_{PU} = 0 \text{ to } 100 \text{ k}\Omega$

The external reset pin ( $\overline{\text{RST}}$ ) resets the microcontroller including the core and all the on-chip peripherals. The external reset sequence is as follows:

1. The external reset pin ( $\overline{\text{RST}}$ ) is asserted for the duration specified by  $T_{\text{MIN}}$  and then de-asserted (see “Reset” on page 1327).
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

To improve noise immunity and/or to delay reset at power up, the  $\overline{\text{RST}}$  input may be connected to an RC network as shown in Figure 5-2 on page 216.

**Figure 5-2. External Circuitry to Extend Power-On Reset**

$R_{PU} = 1 \text{ k}\Omega \text{ to } 100 \text{ k}\Omega$

$C_1 = 1 \text{ nF to } 10 \text{ }\mu\text{F}$

If the application requires the use of an external reset switch, Figure 5-3 on page 217 shows the proper circuitry to use.

**Figure 5-3. Reset Circuit Controlled by Switch**

Typical  $R_{PU} = 10\text{ k}\Omega$

Typical  $R_S = 470\ \Omega$

$C_1 = 10\text{ nF}$

The  $R_{PU}$  and  $C_1$  components define the power-on delay.

The external reset timing is shown in Figure 24-8 on page 1328.

#### 5.2.2.4 Brown-Out Reset (BOR)

The microcontroller provides a brown-out detection circuit that triggers if the power supply ( $V_{DD}$ ) drops below a brown-out threshold voltage ( $V_{BTH}$ ). If a brown-out condition is detected, the system may generate an interrupt or a system reset. The default condition is to generate an interrupt, so BOR must be enabled. Brown-out resets are controlled with the **Power-On and Brown-Out Reset Control (PBORCTL)** register. The **BORI0R** bit in the **PBORCTL** register must be set for a brown-out condition to trigger a reset; if **BORI0R** is clear, an interrupt is generated.

The brown-out reset sequence is as follows:

1. When  $V_{DD}$  drops below  $V_{BTH}$ , an internal BOR condition is set.
2. If the BOR condition exists, an internal reset is asserted.
3. The internal reset is released and the microcontroller fetches and loads the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The result of a brown-out reset is equivalent to that of an assertion of the external RST input, and the reset is held active until the proper  $V_{DD}$  level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in Figure 24-7 on page 1327.

#### 5.2.2.5 Software Reset

Software can reset a specific peripheral or generate a reset to the entire microcontroller.

Peripherals can be individually reset by software via peripheral-specific reset registers available beginning at System Control offset 0x500 (for example the **Watchdog Timer Software Reset (SRWD)** register). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset.

The entire microcontroller, including the core, can be reset by software by setting the SYSRESREQ bit in the **Application Interrupt and Reset Control (APINT)** register. The software-initiated system reset sequence is as follows:

1. A software microcontroller reset is initiated by setting the SYSRESREQ bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The core only can be reset by software by setting the VECTRESET bit in the **APINT** register. The software-initiated core reset sequence is as follows:

1. A core reset is initiated by setting the VECTRESET bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 24-9 on page 1328.

#### 5.2.2.6 Watchdog Timer Reset

The Watchdog Timer module's function is to prevent system hangs. The LM4F231H5QR microcontroller has two Watchdog Timer modules in case one watchdog clock source fails. One watchdog is run off the system clock and the other is run off the Precision Internal Oscillator (PIOSC). Each module operates in the same manner except that because the PIOSC watchdog timer module is in a different clock domain, register accesses must have a time delay between them. The watchdog timer can be configured to generate an interrupt or a non-maskable interrupt to the microcontroller on its first time-out and to generate a reset on its second time-out.

After the watchdog's first time-out event, the 32-bit watchdog counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register and resumes counting down from that value. If the timer counts down to zero again before the first time-out interrupt is cleared, and the reset signal has been enabled, the watchdog timer asserts its reset signal to the microcontroller. The watchdog timer reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.
3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

For more information on the Watchdog Timer module, see "Watchdog Timers" on page 747.

The watchdog reset timing is shown in Figure 24-10 on page 1328.

#### 5.2.3 Non-Maskable Interrupt

The microcontroller has four sources of non-maskable interrupt (NMI):

- The assertion of the NMI signal
- A main oscillator verification error
- The NMISSET bit in the **Interrupt Control and State (INTCTRL)** register in the Cortex™-M4F (see page 161).
- The Watchdog module time-out interrupt when the INTTYPE bit in the **Watchdog Control (WDTCTL)** register is set (see page 753).

Software must check the cause of the interrupt in order to distinguish among the sources.

#### 5.2.3.1 NMI Pin

The NMI signal is an alternate function for either GPIO port pin PD7 or PF0. The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in “General-Purpose Input/Outputs (GPIOs)” on page 623. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function just like the GPIO port pins associated with JTAG/SWD functionality, see page 658. The active sense of the NMI signal is High; asserting the enabled NMI signal above  $V_{IH}$  initiates the NMI interrupt sequence.

#### 5.2.3.2 Main Oscillator Verification Failure

The LM4F231H5QR microcontroller provides a main oscillator verification circuit that generates an error condition if the oscillator is running too fast or too slow. If the main oscillator verification circuit is enabled and a failure occurs, either a power-on reset is generated and control is transferred to the NMI handler, or an interrupt is generated. The MOSCIM bit in the **MOSCCTL** register determines which action occurs. In either case, the system clock source is automatically switched to the PIOSC. If a MOSC failure reset occurs, the NMI handler is used to address the main oscillator verification failure because the necessary code can be removed from the general reset handler, speeding up reset processing. The detection circuit is enabled by setting the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status (MOSCFAIL) bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in “Main Oscillator Verification Circuit” on page 226.

#### 5.2.4 Power Control

The Stellaris microcontroller provides an integrated LDO regulator that is used to provide power to the majority of the microcontroller's internal logic. Figure 5-4 shows the power architecture.

An external LDO may not be used.

**Note:** VDDA must be supplied with a voltage that meets the specification in Table 24-2 on page 1323, or the microcontroller does not function properly. VDDA is the supply for all of the analog circuitry on the device, including the clock circuitry.

Figure 5-4. Power Architecture

## 5.2.5 Clock Control

System control determines the control of clocks in this part.

### 5.2.5.1 Fundamental Clock Sources

There are multiple clock sources for use in the microcontroller:

- **Precision Internal Oscillator (PIOSC).** The precision internal oscillator is an on-chip clock source that is the clock source the microcontroller uses during and following POR. It does not require the use of any external components and provides a clock that is 16 MHz  $\pm 1\%$  at room temperature and  $\pm 3\%$  across temperature. The PIOSC allows for a reduced system cost in applications that require an accurate clock source. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference. Regardless of whether or not the PIOSC is the source for the system clock, the PIOSC can be configured to be the source for the ADC clock as well as the baud clock for the UART and SSI, see “System Control” on page 227.
- **Main Oscillator (MOSC).** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins. If the PLL is being used, the crystal value must be one of the supported frequencies between 5 MHz to 25 MHz

(inclusive). If the PLL is not being used, the crystal may be any one of the supported frequencies between 4 MHz to 25 MHz. The single-ended clock source range is from DC through the specified speed of the microcontroller. The supported crystals are listed in the XTAL bit field in the **RCC** register (see page 249). Note that the MOSC provides the clock source for the USB PLL and must be connected to a crystal or an oscillator.

- **Internal 30-kHz Oscillator.** The internal 30-kHz oscillator provides an operational frequency of 30 kHz  $\pm$  50%. It is intended for use during Deep-Sleep power-saving modes. This power-savings mode benefits from reduced internal switching and also allows the MOSC to be powered down.

The internal system clock (SysClk), is derived from any of the above sources plus two others: the output of the main internal PLL and the precision internal oscillator divided by four (4 MHz  $\pm$  1%). The frequency of the PLL clock reference must be in the range of 5 MHz to 25 MHz (inclusive). Table 5-3 on page 221 shows how the various clock sources can be used in a system.

**Table 5-3. Clock Source Options**

| Clock Source                                               | Drive PLL? |                          | Used as SysClk? |                          |
|------------------------------------------------------------|------------|--------------------------|-----------------|--------------------------|
| Precision Internal Oscillator                              | Yes        | BYPASS = 0, OSCSRC = 0x1 | Yes             | BYPASS = 1, OSCSRC = 0x1 |
| Precision Internal Oscillator divide by 4 (4 MHz $\pm$ 1%) | No         | -                        | Yes             | BYPASS = 1, OSCSRC = 0x2 |
| Main Oscillator                                            | Yes        | BYPASS = 0, OSCSRC = 0x0 | Yes             | BYPASS = 1, OSCSRC = 0x0 |
| Internal 30-kHz Oscillator                                 | No         | -                        | Yes             | BYPASS = 1, OSCSRC = 0x3 |

### 5.2.5.2 Clock Configuration

The **Run-Mode Clock Configuration (RCC)** and **Run-Mode Clock Configuration 2 (RCC2)** registers provide control for the system clock. The **RCC2** register is provided to extend fields that offer additional encodings over the **RCC** register. When used, the **RCC2** register field values are used by the logic over the corresponding field in the **RCC** register. In particular, **RCC2** provides for a larger assortment of clock configuration options. These registers control the following clock functionality:

- Source of clocks in sleep and deep-sleep modes
- System clock derived from PLL or other clock source
- Enabling/disabling of oscillators and PLL
- Clock divisors
- Crystal input selection

**Important:** Write the **RCC** register prior to writing the **RCC2** register. If a subsequent write to the **RCC** register is required, include another register access after writing the **RCC** register and before writing the **RCC2** register.

The configuration of the system clock must not be changed while an EEPROM operation is in process. Software must wait until the **WORKING** bit in the **EEPROM Done Status (EEDONE)** register is clear before making any changes to the system clock.

Figure 5-5 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be individually enabled/disabled. The ADC clock signal can be selected from

the PIOSC, the system clock if the PLL is disabled, or the PLL output divided down to 16 MHz if the PLL is enabled. The PWM clock signal is a synchronous divide of the system clock to provide the PWM circuit with more range (set with PWMDIV in **RCC**).

**Note:** If the ADC module is not using the PIOSC as the clock source, the system clock must be at least 16 MHz. When the USB module is in operation, MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 30 MHz.

### Figure 5-5. Main Clock Tree

**Note:**

- Control provided by **RCC** register bit/field.
- Control provided by **RCC** register bit/field or **RCC2** register bit/field, if overridden with **RCC2** register bit **USERCC2**.
- Control provided by **RCC2** register bit/field.
- Also may be controlled by **DSLPCLKCFG** when in deep sleep mode.
- Control provided by **RCC** register **SYSDIV** field, **RCC2** register **SYSDIV2** field if overridden with **USERCC2** bit, or **[SYSDIV2,SYSDIV2LSB]** if both **USERCC2** and **DIV400** bits are set.
- Control provided by **UARTCC**, **SSICC**, and **ADCCC** register field.

## Communication Clock Sources

In addition to the main clock tree described above, the UART, and SSI modules all have a Clock Control register in the peripheral's register map at offset 0xFC8 that can be used to select the clock

source for the module's baud clock. Users can choose between the system clock, which is the default source for the baud clock, and the PIOSC. Note that there may be special considerations when using the PIOSC as the baud clock. For more information, see the Clock Control register description in the chapter describing the operation of the module.

### Using the SYSDIV and SYSDIV2 Fields

In the **RCC** register, the SYSDIV field specifies which divisor is used to generate the system clock from either the PLL output or the oscillator source (depending on how the BYPASS bit in this register is configured). When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. Table 5-4 shows how the SYSDIV encoding affects the system clock frequency, depending on whether the PLL is used (BYPASS=0) or another clock source is used (BYPASS=1). The divisor is equivalent to the SYSDIV encoding plus 1. For a list of possible clock sources, see Table 5-3 on page 221.

**Table 5-4. Possible System Clock Frequencies Using the SYSDIV Field**

| SYSDIV | Divisor | Frequency (BYPASS=0) | Frequency (BYPASS=1)      | StellarisWare® Parameter <sup>a</sup> |
|--------|---------|----------------------|---------------------------|---------------------------------------|
| 0x0    | /1      | reserved             | Clock source frequency/2  | SYSCTL_SYSDIV_1 <sup>b</sup>          |
| 0x1    | /2      | reserved             | Clock source frequency/2  | SYSCTL_SYSDIV_2                       |
| 0x2    | /3      | 66.67 MHz            | Clock source frequency/3  | SYSCTL_SYSDIV_3                       |
| 0x3    | /4      | 50 MHz               | Clock source frequency/4  | SYSCTL_SYSDIV_4                       |
| 0x4    | /5      | 40 MHz               | Clock source frequency/5  | SYSCTL_SYSDIV_5                       |
| 0x5    | /6      | 33.33 MHz            | Clock source frequency/6  | SYSCTL_SYSDIV_6                       |
| 0x6    | /7      | 28.57 MHz            | Clock source frequency/7  | SYSCTL_SYSDIV_7                       |
| 0x7    | /8      | 25 MHz               | Clock source frequency/8  | SYSCTL_SYSDIV_8                       |
| 0x8    | /9      | 22.22 MHz            | Clock source frequency/9  | SYSCTL_SYSDIV_9                       |
| 0x9    | /10     | 20 MHz               | Clock source frequency/10 | SYSCTL_SYSDIV_10                      |
| 0xA    | /11     | 18.18 MHz            | Clock source frequency/11 | SYSCTL_SYSDIV_11                      |
| 0xB    | /12     | 16.67 MHz            | Clock source frequency/12 | SYSCTL_SYSDIV_12                      |
| 0xC    | /13     | 15.38 MHz            | Clock source frequency/13 | SYSCTL_SYSDIV_13                      |
| 0xD    | /14     | 14.29 MHz            | Clock source frequency/14 | SYSCTL_SYSDIV_14                      |
| 0xE    | /15     | 13.33 MHz            | Clock source frequency/15 | SYSCTL_SYSDIV_15                      |
| 0xF    | /16     | 12.5 MHz (default)   | Clock source frequency/16 | SYSCTL_SYSDIV_16                      |

a. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

b. SYSCTL\_SYSDIV\_1 does not set the USESYSDIV bit. As a result, using this parameter without enabling the PLL results in the system clock having the same frequency as the clock source.

The SYSDIV2 field in the **RCC2** register is 2 bits wider than the SYSDIV field in the **RCC** register so that additional larger divisors up to /64 are possible, allowing a lower system clock frequency for improved Deep Sleep power consumption. When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. The divisor is equivalent to the SYSDIV2 encoding plus 1. Table 5-5 shows how the SYSDIV2 encoding affects the system clock frequency, depending on whether the PLL is used (BYPASS2=0) or another clock source is used (BYPASS2=1). For a list of possible clock sources, see Table 5-3 on page 221.

**Table 5-5. Examples of Possible System Clock Frequencies Using the SYSDIV2 Field**

| SYSDIV2 | Divisor | Frequency (BYPASS2=0) | Frequency (BYPASS2=1)    | StellarisWare Parameter <sup>a</sup> |
|---------|---------|-----------------------|--------------------------|--------------------------------------|
| 0x00    | /1      | reserved              | Clock source frequency/2 | SYSCTL_SYSDIV_1 <sup>b</sup>         |

**Table 5-5. Examples of Possible System Clock Frequencies Using the SYSDIV2 Field  
(continued)**

| SYSDIV2 | Divisor | Frequency (BYPASS2=0) | Frequency (BYPASS2=1)     | StellarisWare Parameter <sup>a</sup> |
|---------|---------|-----------------------|---------------------------|--------------------------------------|
| 0x01    | /2      | reserved              | Clock source frequency/2  | SYSCTL_SYSDIV_2                      |
| 0x02    | /3      | 66.67 MHz             | Clock source frequency/3  | SYSCTL_SYSDIV_3                      |
| 0x03    | /4      | 50 MHz                | Clock source frequency/4  | SYSCTL_SYSDIV_4                      |
| 0x04    | /5      | 40 MHz                | Clock source frequency/5  | SYSCTL_SYSDIV_5                      |
| ...     | ...     | ...                   | ...                       | ...                                  |
| 0x09    | /10     | 20 MHz                | Clock source frequency/10 | SYSCTL_SYSDIV_10                     |
| ...     | ...     | ...                   | ...                       | ...                                  |
| 0x3F    | /64     | 3.125 MHz             | Clock source frequency/64 | SYSCTL_SYSDIV_64                     |

a. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

b. SYSCTL\_SYSDIV\_1 does not set the USESYSDIV bit. As a result, using this parameter without enabling the PLL results in the system clock having the same frequency as the clock source.

To allow for additional frequency choices when using the PLL, the DIV400 bit is provided along with the SYSDIV2LSB bit. When the DIV400 bit is set, bit 22 becomes the LSB for SYSDIV2. In this situation, the divisor is equivalent to the (SYSDIV2 encoding with SYSDIV2LSB appended) plus one. Table 5-6 shows the frequency choices when DIV400 is set. When the DIV400 bit is clear, SYSDIV2LSB is ignored, and the system clock frequency is determined as shown in Table 5-5 on page 223.

**Table 5-6. Examples of Possible System Clock Frequencies with DIV400=1**

| SYSDIV2 | SYSDIV2LSB | Divisor | Frequency (BYPASS2=0) <sup>a</sup> | StellarisWare Parameter <sup>b</sup> |
|---------|------------|---------|------------------------------------|--------------------------------------|
| 0x00    | reserved   | /2      | reserved                           | -                                    |
| 0x01    | 0          | /3      | reserved                           | -                                    |
|         | 1          | /4      | reserved                           | -                                    |
| 0x02    | 0          | /5      | 80 MHz                             | SYSCTL_SYSDIV_2_5                    |
|         | 1          | /6      | 66.67 MHz                          | SYSCTL_SYSDIV_3                      |
| 0x03    | 0          | /7      | reserved                           | -                                    |
|         | 1          | /8      | 50 MHz                             | SYSCTL_SYSDIV_4                      |
| 0x04    | 0          | /9      | 44.44 MHz                          | SYSCTL_SYSDIV_4_5                    |
|         | 1          | /10     | 40 MHz                             | SYSCTL_SYSDIV_5                      |
| ...     | ...        | ...     | ...                                | ...                                  |
| 0x3F    | 0          | /127    | 3.15 MHz                           | SYSCTL_SYSDIV_63_5                   |
|         | 1          | /128    | 3.125 MHz                          | SYSCTL_SYSDIV_64                     |

a. Note that DIV400 and SYSDIV2LSB are only valid when BYPASS2=0.

b. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

### 5.2.5.3 Precision Internal Oscillator Operation (PIOSC)

The microcontroller powers up with the PIOSC running. If another clock source is desired, the PIOSC must remain enabled as it is used for internal functions. The PIOSC can only be disabled during Deep-Sleep mode. It can be powered down by setting the IOSCDIS bit in the **RCC** register.

The PIOSC generates a 16-MHz clock with a  $\pm 1\%$  accuracy at room temperatures. Across the extended temperature range, the accuracy is  $\pm 3\%$ . At the factory, the PIOSC is set to 16 MHz at

room temperature, however, the frequency can be trimmed for other voltage or temperature conditions using software in one of two ways:

- Default calibration: clear the UTEN bit and set the UPDATE bit in the **Precision Internal Oscillator Calibration (PIOCCAL)** register.
- User-defined calibration: The user can program the UT value to adjust the PIOSC frequency. As the UT value increases, the generated period increases. To commit a new UT value, first set the UTEN bit, then program the UT field, and then set the UPDATE bit. The adjustment finishes within a few clock periods and is glitch free.

#### 5.2.5.4 Crystal Configuration for the Main Oscillator (MOSC)

The main oscillator supports the use of a select number of crystals from 4 to 25 MHz.

The XTAL bit in the **RCC** register (see page 249) describes the available crystal choices and default programming values.

Software configures the **RCC** register XTAL field with the crystal number. If the PLL is used in the design, the XTAL field value is internally translated to the PLL settings.

#### 5.2.5.5 Main PLL Frequency Configuration

The main PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the main PLL to drive the output. The PLL operates at 400 MHz, but is divided by two prior to the application of the output divisor, unless the DIV400 bit in the **RCC2** register is set.

To configure the PIOSC to be the clock source for the main PLL, program the OSCRC2 field in the **Run-Mode Clock Configuration 2 (RCC2)** register to be 0x1.

If the main oscillator provides the clock reference to the main PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLFREQn)** registers (see page 264). The internal translation provides a translation within  $\pm 1\%$  of the targeted PLL VCO frequency. Table 24-10 on page 1329 shows the actual PLL frequency and error for a given crystal choice.

The Crystal Value field (XTAL) in the **Run-Mode Clock Configuration (RCC)** register (see page 249) describes the available crystal choices and default programming of the **PLLFREQn** registers. Any time the XTAL field changes, the new settings are translated and the internal PLL settings are updated.

#### 5.2.5.6 USB PLL Frequency Configuration

The USB PLL is disabled by default during power-on reset and is enabled later by software. The USB PLL must be enabled and running for proper USB function. The main oscillator is the only clock reference for the USB PLL. The USB PLL is enabled by clearing the USBPWRDN bit of the **RCC2** register. The XTAL bit field (Crystal Value) of the **RCC** register describes the available crystal choices. The main oscillator must be connected to one of the following crystal values in order to correctly generate the USB clock: 5, 6, 8, 10, 12, 16, 18, 20, 24, or 25 MHz. Only these crystals provide the necessary USB PLL VCO frequency to conform with the USB timing specifications.

#### 5.2.5.7 PLL Modes

Both PLLs have two modes of operation: Normal and Power-Down

- Normal: The PLL multiplies the input clock reference and drives the output.

- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the **RCC/RCC2** register fields (see page 249 and page 256).

#### 5.2.5.8 PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is  $T_{\text{READY}}$  (see Table 24-9 on page 1329). During the relock time, the affected PLL is not usable as a clock reference. Software can poll the LOCK bit in the **PLL Status (PLLSTAT)** register to determine when the PLL has locked.

Either PLL is changed by one of the following:

- Change to the XTAL value in the **RCC** register—writes of the same value do not cause a relock.
- Change in the PLL from Power-Down to Normal mode.

A counter clocked by the system clock is used to measure the  $T_{\text{READY}}$  requirement. The down counter is set to 0x200 if the PLL is powering up. If the M or N values in the **PLLFREQn** registers are changed, the counter is set to 0xC0. Hardware is provided to keep the PLL from being used as a system clock until the  $T_{\text{READY}}$  condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RCC/RCC2** register is switched to use the PLL.

If the main PLL is enabled and the system clock is switched to use the PLL in one step, the system control hardware continues to clock the microcontroller from the oscillator selected by the **RCC/RCC2** register until the main PLL is stable ( $T_{\text{READY}}$  time met), after which it changes to the PLL. Software can use many methods to ensure that the system is clocked from the main PLL, including periodically polling the PLLLRIS bit in the **Raw Interrupt Status (RIS)** register, and enabling the PLL Lock interrupt.

The USB PLL is not protected during the lock time ( $T_{\text{READY}}$ ), and software should ensure that the USB PLL has locked before using the interface. Software can use many methods to ensure the  $T_{\text{READY}}$  period has passed, including periodically polling the USBPLLLRIS bit in the **Raw Interrupt Status (RIS)** register, and enabling the USB PLL Lock interrupt.

#### 5.2.5.9 Main Oscillator Verification Circuit

The clock control includes circuitry to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, and if the MOSCIM bit in the **MOSCCTL** register is clear, then the following sequence is performed by the hardware:

1. The MOSCFAIL bit in the **Reset Cause (RESC)** register is set.
2. The system clock is switched from the main oscillator to the PIOSC.
3. An internal power-on reset is initiated.
4. Reset is de-asserted and the processor is directed to the NMI handler during the reset sequence.

if the MOSCIM bit in the **MOSCCTL** register is set, then the following sequence is performed by the hardware:

1. The system clock is switched from the main oscillator to the PIOSC.
2. The MOFRIS bit in the **RIS** register is set to indicate a MOSC failure.

## 5.2.6 System Control

For power-savings purposes, the peripheral-specific **RCGCx**, **SCGCx**, and **DCGCx** registers (for example, **RCGCWD**) control the clock gating logic for that peripheral or block in the system while the microcontroller is in Run, Sleep, and Deep-Sleep mode, respectively. These registers are located in the System Control register map starting at offsets 0x600, 0x700, and 0x800, respectively. There must be a delay of 3 system clocks after a peripheral module clock is enabled in the **RCGC** register before any module registers are accessed.

---

**Important:** To support legacy software, the **RCGCn**, **SCGCn**, and **DCGCn** registers are available at offsets 0x100 - 0x128. A write to any of these legacy registers also writes the corresponding bit in the peripheral-specific **RCGCx**, **SCGCx**, and **DCGCx** registers. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. It is recommended that new software use the new registers and not rely on legacy operation.

If software uses a peripheral-specific register to write a legacy peripheral (such as **TIMER0**), the write causes proper operation, but the value of that bit is not reflected in the legacy register. Any bits that are changed by writing to a legacy register can be read back correctly with a read of the legacy register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

---

There are three levels of operation for the microcontroller defined as:

- Run mode
- Sleep mode
- Deep-Sleep mode

The following sections describe the different modes in detail.

---

**Caution –** If the Cortex-M4F Debug Access Port (DAP) has been enabled, and the device wakes from a low power sleep or deep-sleep mode, the core may start executing code before all clocks to peripherals have been restored to their Run mode configuration. The DAP is usually enabled by software tools accessing the JTAG or SWD interface when debugging or flash programming. If this condition occurs, a Hard Fault is triggered when software accesses a peripheral with an invalid clock.

A software delay loop can be used at the beginning of the interrupt routine that is used to wake up a system from a WFI (Wait For Interrupt) instruction. This stalls the execution of any code that accesses a peripheral register that might cause a fault. This loop can be removed for production software as the DAP is most likely not enabled during normal execution.

Because the DAP is disabled by default (power on reset), the user can also power cycle the device. The DAP is not enabled unless it is enabled through the JTAG or SWD interface.

---

### 5.2.6.1 Run Mode

In Run mode, the microcontroller actively executes code. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the peripheral-specific **RCGC** registers. The system clock can be any of the available clock sources including the PLL.

### 5.2.6.2 Sleep Mode

In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor and the memory subsystem are not clocked and therefore no longer execute code. Sleep mode is entered by the Cortex-M4F core executing a WFI (Wait for Interrupt) instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 115 for more details.

Peripherals are clocked that are enabled in the peripheral-specific **SCGC** registers when auto-clock gating is enabled (see the **RCC** register) or the peripheral-specific **RCGC** registers when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

---

**Important:** Before executing the WFI instruction, software must confirm that the EEPROM is not busy by checking to see that the WORKING bit in the **EEPROM Done Status (EEDONE)** register is clear.

---

### 5.2.6.3 Deep-Sleep Mode

In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Run mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the microcontroller to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Deep-Sleep mode is entered by first setting the SLEEPDEEP bit in the **System Control (SYSCTRL)** register (see page 167) and then executing a WFI instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 115 for more details.

The Cortex-M4F processor core and the memory subsystem are not clocked in Deep-Sleep mode. Peripherals are clocked that are enabled in the peripheral-specific **DCGC** registers when auto-clock gating is enabled (see the **RCC** register) or the peripheral-specific **RCGC** registers when auto-clock gating is disabled. The system clock source is specified in the **DSLPCCLKCFG** register. When the **DSLPCCLKCFG** register is used, the internal oscillator source is powered up, if necessary, and other clocks are powered down. If the PLL is running at the time of the WFI instruction, hardware powers the PLL down and overrides the SYSDIV field of the active **RCC/RCC2** register, to be determined by the DSDIVORIDE setting in the **DSLPCCLKCFG** register, up to /16 or /64 respectively. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration. If the PIOSC is used as the PLL reference clock source, it may continue to provide the clock during Deep-Sleep. See page 260.

---

**Important:** Before executing the WFI instruction, software must confirm that the EEPROM is not busy by checking to see that the WORKING bit in the **EEPROM Done Status (EEDONE)** register is clear.

---

To provide the lowest possible Deep-Sleep power consumption as well the ability to wake the processor from a peripheral without reconfiguring the peripheral for a change in clock, some of the communications modules have a Clock Control register at offset 0xFC8 in the module register space. The CS field in the Clock Control register allows the user to select the PIOSC as the clock source for the module's baud clock. When the microcontroller enters Deep-Sleep mode, the PIOSC becomes

the source for the module clock as well, which allows the transmit and receive FIFOs to continue operation while the part is in Deep-Sleep. Figure 5-6 on page 229 shows how the clocks are selected.

**Figure 5-6. Module Clock Selection**

## 5.3 Initialization and Configuration

The PLL is configured using direct register writes to the **RCC/RCC2** register. If the **RCC2** register is being used, the **USERCC2** bit must be set and the appropriate **RCC2** bit/field is used. The steps required to successfully change the PLL-based system clock are:

1. Bypass the PLL and system clock divider by setting the **BYPASS** bit and clearing the **USESYS** bit in the **RCC** register, thereby configuring the microcontroller to run off a "raw" clock source and allowing for the new PLL configuration to be validated before switching the system clock to the PLL.
2. Select the crystal value (**XTAL**) and oscillator source (**OSCSRC**), and clear the **PWRDN** bit in **RCC/RCC2**. Setting the **XTAL** field automatically pulls valid PLL configuration data for the appropriate crystal, and clearing the **PWRDN** bit powers and enables the PLL and its output.
3. Select the desired system divider (**SYSDIV**) in **RCC/RCC2** and set the **USESYS** bit in **RCC**. The **SYSDIV** field determines the system frequency for the microcontroller.
4. Wait for the PLL to lock by polling the **PLLLRIS** bit in the **Raw Interrupt Status (RIS)** register.
5. Enable use of the PLL by clearing the **BYPASS** bit in **RCC/RCC2**.

## 5.4 Register Map

Table 5-7 on page 230 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

**Note:** Spaces in the System Control register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Additional Flash and ROM registers defined in the System Control register space are described in the "Internal Memory" on page 501.

Table 5-7. System Control Register Map

| Offset                          | Name      | Type  | Reset       | Description                                                    | See page |

## 5.5 System Control Register Descriptions

All addresses given are relative to the System Control base address of 0x400F.E000. Registers provided for legacy software support only are listed in “System Control Legacy Register Descriptions” on page 431.

## Register 1: Device Identification 0 (DID0), offset 0x000

This register identifies the version of the microcontroller. Each microcontroller is uniquely identified by the combined values of the CLASS field in the **DID0** register and the PARTNO field in the **DID1** register.

### Device Identification 0 (DID0)

Base 0x400F.E000

Offset 0x000

## Register 2: Device Identification 1 (DID1), offset 0x004

This register identifies the device family, part number, temperature range, pin count, and package type. Each microcontroller is uniquely identified by the combined values of the CLASS field in the **DID0** register and the PARTNO field in the **DID1** register.

### Device Identification 1 (DID1)

Base 0x400F.E000

Offset 0x004

Type RO, reset -

## Register 4: Raw Interrupt Status (RIS), offset 0x050

This register indicates the status for system control raw interrupts. An interrupt is sent to the interrupt controller if the corresponding bit in the **Interrupt Mask Control (IMC)** register is set. Writing a 1 to the corresponding bit in the **Masked Interrupt Status and Clear (MISC)** register clears an interrupt status bit.

### Raw Interrupt Status (RIS)

## Register 5: Interrupt Mask Control (IMC), offset 0x054

This register contains the mask bits for system control raw interrupts. A raw interrupt, indicated by a bit being set in the **Raw Interrupt Status (RIS)** register, is sent to the interrupt controller if the corresponding bit in this register is set.

### Interrupt Mask Control (IMC)

## Register 6: Masked Interrupt Status and Clear (MISC), offset 0x058

On a read, this register gives the current masked status value of the corresponding interrupt in the **Raw Interrupt Status (RIS)** register. All of the bits are R/W1C, thus writing a 1 to a bit clears the corresponding raw interrupt bit in the **RIS** register (see page 241).

#### Value Description

- 1 When read, a 1 indicates that an unmasked interrupt was signaled because sufficient time has passed for the MOSC PLL to lock.  
Writing a 1 to this bit clears it and also the MOSCPUPRIS bit in the **RIS** register.
- 0 When read, a 0 indicates that sufficient time has not passed for the MOSC PLL to lock.  
A write of 0 has no effect on the state of this bit.

To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                 |

## Register 7: Reset Cause (RESC), offset 0x05C

This register is set with the reset cause after reset. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an power-on reset is the cause, in which case, all bits other than POR in the **RESC** register are cleared.

#### Value Description

- 1 When read, this bit indicates that the MOSC circuit was enabled for clock validation and failed while the MOSCIM bit in the **MOSCCTL** register is clear, generating a reset event.
- 0 When read, this bit indicates that a MOSC failure has not generated a reset since the previous power-on reset.  
Writing a 0 to this bit clears it.

## Register 8: Run-Mode Clock Configuration (RCC), offset 0x060

The bits in this register configure the system clock and oscillators.

**Important:** Write the **RCC** register prior to writing the **RCC2** register. If a subsequent write to the **RCC** register is required, include another register access after writing the **RCC** register and before writing the **RCC2** register.

The USEPWMDIV and PWMDIV fields in the **PWM Peripheral Configuration (PWMPC)** register should be used to control the PWM clock. To support legacy software, the USEPWMDIV and PWMDIV fields in this register are available. A write to these legacy fields also writes the corresponding fields in the **PWMPC** register. If these fields are changed by writing to this register, they can be read back correctly with a read of this register. If software uses the **PWMPC** register to configure the PWM clock, the PWM clock operates as specified, but the value of USEPWMDIV and PWMDIV fields in this register are not modified.

## Register 9: GPIO High-Performance Bus Control (GPIOHBCTL), offset 0x06C

This register controls which internal bus is used to access each GPIO port. When a bit is clear, the corresponding GPIO port is accessed across the legacy Advanced Peripheral Bus (APB) bus and through the APB memory aperture. When a bit is set, the corresponding port is accessed across the Advanced High-Performance Bus (AHB) bus and through the AHB memory aperture. Each GPIO port can be individually configured to use AHB or APB, but may be accessed only through one aperture. The AHB bus provides better back-to-back access performance than the APB bus. The address aperture in the memory map changes for the ports that are enabled for AHB access (see Table 9-6 on page 632).

**Important:** Ports K-N and P-Q are only available on the AHB bus, and therefore the corresponding bits reset to 1. If one of these bits is cleared, the corresponding port is disabled. If any of these ports is in use, read-modify-write operations should be used to change the value of this register so that these ports remain enabled.

## Register 10: Run-Mode Clock Configuration 2 (RCC2), offset 0x070

This register overrides the **RCC** equivalent register fields, as shown in Table 5-8, when the **USERCC2** bit is set, allowing the extended capabilities of the **RCC2** register to be used while also providing a means to be backward-compatible to previous parts. Each **RCC2** field that supersedes an **RCC** field is located at the same LSB bit position; however, some **RCC2** fields are larger than the corresponding **RCC** field.

**Table 5-8. RCC2 Fields that Override RCC Fields**

| RCC2 Field...        | Overrides RCC Field |
|----------------------|---------------------|
| SYSDIV2, bits[28:23] | SYSDIV, bits[26:23] |
| PWRDN2, bit[13]      | PWRDN, bit[13]      |
| BYPASS2, bit[11]     | BYPASS, bit[11]     |
| OSCSRC2, bits[6:4]   | OSCSRC, bits[5:4]   |

**Important:** Write the **RCC** register prior to writing the **RCC2** register. If a subsequent write to the **RCC** register is required, include another register access after writing the **RCC** register and before writing the **RCC2** register.

## Register 11: Main Oscillator Control (MOSCCTL), offset 0x07C

This register provides control over the features of the main oscillator, including the ability to enable the MOSC clock verification circuit, what action to take when the MOSC fails, and whether or not a crystal is connected. When enabled, this circuit monitors the frequency of the MOSC to verify that the oscillator is operating within specified limits. If the clock goes invalid after being enabled, the microcontroller issues a power-on reset and reboots to the NMI handler or generates an interrupt.

## Register 13: System Properties (SYSPROP), offset 0x14C

This register provides information on whether certain System Control properties are present on the microcontroller.

### System Properties (SYSPROP)

Base 0x400F.E000

Offset 0x14C

Type RO, reset 0x0000.1D31

**Register 15: PLL Frequency 0 (PLLREQ0), offset 0x160**

This register always contains the current M value presented to the system PLL.

The PLL frequency can be calculated using the following equation:

$$\text{PLL frequency} = (\text{XTAL frequency} * \text{MDIV}) / ((Q + 1) * (N + 1))$$

where

$$\text{MDIV} = \text{MINT} + (\text{MFRAC} / 1024)$$

The Q and N values are shown in the **PLLREQ1** register. Table 24-10 on page 1329 shows the M, Q, and N values as well as the resulting PLL frequency for the various XTAL configurations.

**Register 18: Watchdog Timer Peripheral Present (PPWD), offset 0x300**

The **PPWD** register provides software information regarding the watchdog modules.

**Important:** This register should be used to determine which watchdog timers are implemented on this microcontroller. However, to support legacy software, the **DC1** register is available. A read of the **DC1** register correctly identifies if a legacy module is present.

## Register 19: 16/32-Bit General-Purpose Timer Peripheral Present (PPTIMER), offset 0x304

The **PPTIMER** register provides software information regarding the 16/32-bit general-purpose timer modules.

**Important:** This register should be used to determine which timers are implemented on this microcontroller. However, to support legacy software, the **DC2** register is available. A read of the **DC2** register correctly identifies if a legacy module is present. Software must use this register to determine if a module that is not supported by the **DC2** register is present.

## Register 21: Micro Direct Memory Access Peripheral Present (PPDMA), offset 0x30C

The **PPDMA** register provides software information regarding the  $\mu$ DMA module.

**Important:** This register should be used to determine if the  $\mu$ DMA module is implemented on this microcontroller. However, to support legacy software, the **DC7** register is available. A read of the **DC7** register correctly identifies if the  $\mu$ DMA module is present.

## Register 23: Universal Asynchronous Receiver/Transmitter Peripheral Present (PPUART), offset 0x318

The **PPUART** register provides software information regarding the UART modules.

**Important:** This register should be used to determine which UART modules are implemented on this microcontroller. However, to support legacy software, the **DC2** register is available. A read of the **DC2** register correctly identifies if a legacy UART module is present. Software must use this register to determine if a module that is not supported by the **DC2** register is present.

**Register 27: Controller Area Network Peripheral Present (PPCAN), offset 0x334**

The **PPCAN** register provides software information regarding the CAN modules.

**Important:** This register should be used to determine which CAN modules are implemented on this microcontroller. However, to support legacy software, the **DC1** register is available. A read of the **DC1** register correctly identifies if a legacy CAN module is present.

## Register 31: Quadrature Encoder Interface Peripheral Present (PPQEI), offset 0x344

The **PPQEI** register provides software information regarding the QEI modules.

**Important:** This register should be used to determine which QEI modules are implemented on this microcontroller. However, to support legacy software, the **DC2** register is available. A read of the **DC2** register correctly identifies if a legacy QEI module is present.

### Register 34: Watchdog Timer Software Reset (SRWD), offset 0x500

The **SRWD** register provides software the capability to reset the available watchdog modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRWD** register. While the **SRWD** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRWD** bit.

There may be latency from the clearing of the **SRWD** bit to when the peripheral is ready for use. Software can check the corresponding **PRWD** bit to be sure.

**Important:** This register should be used to reset the watchdog modules. To support legacy software, the **SRCR0** register is available. Setting a bit in the **SRCR0** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR0** register can be read back correctly when reading the **SRCR0** register. If software uses this register to reset a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 35: 16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504

The **SRTIMER** register provides software the capability to reset the available 16/32-bit timer modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the timer modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRTIMER** register. While the **SRTIMER** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRTIMER** bit.

There may be latency from the clearing of the **SRTIMER** bit to when the peripheral is ready for use. Software can check the corresponding **PRTIMER** bit to be sure.

**Important:** This register should be used to reset the timer modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as Timer 1), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 36: General-Purpose Input/Output Software Reset (SRGPIO), offset 0x508

The **SRGPIO** register provides software the capability to reset the available GPIO modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the GPIO modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRGPIO** register. While the **SRGPIO** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRGPIO** bit.

There may be latency from the clearing of the **SRGPIO** bit to when the peripheral is ready for use. Software can check the corresponding **PRGPIO** bit to be sure.

**Important:** This register should be used to reset the GPIO modules. To support legacy software, the **SRCR2** register is available. Setting a bit in the **SRCR2** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR2** register can be read back correctly when reading the **SRCR2** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 37: Micro Direct Memory Access Software Reset (SRDMA), offset 0x50C

The **SRDMA** register provides software the capability to reset the available  $\mu$ DMA module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the  $\mu$ DMA module and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRDMA** register. While the **SRDMA** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRDMA** bit.

There may be latency from the clearing of the **SRDMA** bit to when the peripheral is ready for use. Software can check the corresponding **PRDMA** bit to be sure.

**Important:** This register should be used to reset the  $\mu$ DMA module. To support legacy software, the **SRCR2** register is available. Setting the UDMA bit in the **SRCR2** register also resets the  $\mu$ DMA module. If the UDMA bit is set by writing to the **SRCR2** register, it can be read back correctly when reading the **SRCR2** register. If software uses this register to reset the  $\mu$ DMA module, the write causes proper operation, but the value of the UDMA bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 38: Universal Asynchronous Receiver/Transmitter Software Reset (SRUART), offset 0x518

The **SRUART** register provides software the capability to reset the available UART modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the UART modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRUART** register. While the **SRUART** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRUART** bit.

There may be latency from the clearing of the **SRUART** bit to when the peripheral is ready for use. Software can check the corresponding **PRUART** bit to be sure.

**Important:** This register should be used to reset the UART modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 39: Synchronous Serial Interface Software Reset (SRSSI), offset 0x51C

The **SRSSI** register provides software the capability to reset the available SSI modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the SSI modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRSSI** register. While the **SRSSI** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRSSI** bit.

There may be latency from the clearing of the **SRSSI** bit to when the peripheral is ready for use. Software can check the corresponding **PRSSI** bit to be sure.

**Important:** This register should be used to reset the SSI modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 40: Inter-Integrated Circuit Software Reset (SRI2C), offset 0x520

The **SRI2C** register provides software the capability to reset the available I<sup>2</sup>C modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the I<sup>2</sup>C modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRI2C** register. While the **SRI2C** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRI2C** bit.

There may be latency from the clearing of the **SRI2C** bit to when the peripheral is ready for use. Software can check the corresponding **PRi2C** bit to be sure.

**Important:** This register should be used to reset the I<sup>2</sup>C modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. Software must use this register to reset modules that are not present in the legacy registers. If software uses this register to reset a legacy peripheral (such as I2C0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 41: Universal Serial Bus Software Reset (SRUSB), offset 0x528

The **SRUSB** register provides software the capability to reset the available USB module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the USB module and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRUSB** register. While the **SRUSB** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRUSB** bit.

There may be latency from the clearing of the **SRUSB** bit to when the peripheral is ready for use. Software can check the corresponding **PRUSB** bit to be sure.

**Important:** This register should be used to reset the USB module. To support legacy software, the **SRCR2** register is available. Setting the USB0 bit in the **SRCR2** register also resets the USB module. If the USB0 bit is set by writing to the **SRCR2** register, it can be read back correctly when reading the **SRCR2** register. If software uses this register to reset the USB module, the write causes proper operation, but the value of the USB0 bit is not reflected in the **SRCR2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 42: Controller Area Network Software Reset (SRCAN), offset 0x534

The **SRCAN** register provides software the capability to reset the available CAN modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the CAN modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRCAN** register. While the **SRCAN** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRCAN** bit.

There may be latency from the clearing of the **SRCAN** bit to when the peripheral is ready for use. Software can check the corresponding **PRCAN** bit to be sure.

**Important:** This register should be used to reset the CAN modules. To support legacy software, the **SRCR0** register is available. Setting a bit in the **SRCR0** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR0** register can be read back correctly when reading the **SRCR0** register. If software uses this register to reset a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

**Register 43: Analog-to-Digital Converter Software Reset (SRADC), offset 0x538**

The **SRADC** register provides software the capability to reset the available ADC modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the ADC modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRADC** register. While the **SRADC** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRADC** bit.

There may be latency from the clearing of the **SRADC** bit to when the peripheral is ready for use. Software can check the corresponding **PRADC** bit to be sure.

**Important:** This register should be used to reset the ADC modules. To support legacy software, the **SRCR0** register is available. Setting a bit in the **SRCR0** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR0** register can be read back correctly when reading the **SRCR0** register. If software uses this register to reset a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 44: Analog Comparator Software Reset (SRACMP), offset 0x53C

The **SRACMP** register provides software the capability to reset the available analog comparator module. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the analog comparator module and has the same bit polarity as the corresponding **SRCRn** bits.

A block is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRACMP** register. While the **SRACMP** bit is 1, the module is held in reset.
2. Software completes the reset process by clearing the **SRACMP** bit.

There may be latency from the clearing of the **SRACMP** bit to when the module is ready for use. Software can check the corresponding **PRACMP** bit to be sure.

**Important:** This register should be used to reset the analog comparator module. To support legacy software, the **SRCR1** register is available. Setting any of the COMPn bits in the **SRCR0** register also resets the analog comparator module. If any of the COMPn bits are set by writing to the **SRCR1** register, it can be read back correctly when reading the **SRCR0** register. If software uses this register to reset the analog comparator module, the write causes proper operation, but the value of R0 is not reflected by the COMPn bits in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

**Register 45: Pulse Width Modulator Software Reset (SRPWM), offset 0x540**

The **SRPWM** register provides software the capability to reset the available PWM modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the PWM modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRPWM** register. While the **SRPWM** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRPWM** bit.

There may be latency from the clearing of the **SRPWM** bit to when the peripheral is ready for use. Software can check the corresponding **PRPWM** bit to be sure.

**Important:** This register should be used to reset the PWM modules. To support legacy software, the **SRCR0** register is available. Setting the PWM bit in the **SRCR0** register also resets the PWM0 module. If the PWM bit is changed by writing to the **SRCR0** register, it can be read back correctly when reading the **SRCR0** register. Software must use this register to reset PWM1, which is not present in the legacy registers. If software uses this register to reset PWM0, the write causes proper operation, but the value of that bit is not reflected in the **SRCR0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 46: Quadrature Encoder Interface Software Reset (SRQEI), offset 0x544

The **SRQEI** register provides software the capability to reset the available QEI modules. This register provides the same capability as the legacy **Software Reset Control n SRCRn** registers specifically for the QEI modules and has the same bit polarity as the corresponding **SRCRn** bits.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRQEI** register. While the **SRQEI** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRQEI** bit.

There may be latency from the clearing of the **SRQEI** bit to when the peripheral is ready for use. Software can check the corresponding **PRQEI** bit to be sure.

**Important:** This register should be used to reset the QEI modules. To support legacy software, the **SRCR1** register is available. Setting a bit in the **SRCR1** register also resets the corresponding module. Any bits that are changed by writing to the **SRCR1** register can be read back correctly when reading the **SRCR1** register. If software uses this register to reset a legacy peripheral (such as QEIO), the write causes proper operation, but the value of that bit is not reflected in the **SRCR1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 48: 32/64-Bit Wide General-Purpose Timer Software Reset (SRWTIMER), offset 0x55C

The **SRWTIMER** register provides software the capability to reset the available 32/64-bit wide timer modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRWTIMER** register. While the **SRWTIMER** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRWTIMER** bit.

There may be latency from the clearing of the **SRWTIMER** bit to when the peripheral is ready for use. Software can check the corresponding **PRWTIMER** bit to be sure.

## Register 49: Watchdog Timer Run Mode Clock Gating Control (RCGCWD), offset 0x600

The **RCGCWD** register provides software the capability to enable and disable watchdog modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the watchdog modules. To support legacy software, the **RCGC0** register is available. A write to the **RCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC0** register can be read back correctly with a read of the **RCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 50: 16/32-Bit General-Purpose Timer Run Mode Clock Gating Control (RCGCTIMER), offset 0x604

The **RCGCTIMER** register provides software the capability to enable and disable 16/32-bit timer modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the timer modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 51: General-Purpose Input/Output Run Mode Clock Gating Control (RCGCGPIO), offset 0x608

The **RCGCGPIO** register provides software the capability to enable and disable GPIO modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the GPIO modules. To support legacy software, the **RCGC2** register is available. A write to the **RCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC2** register can be read back correctly with a read of the **RCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **RCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 52: Micro Direct Memory Access Run Mode Clock Gating Control (RCGCDMA), offset 0x60C

The **RCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module. To support legacy software, the **RCGC2** register is available. A write to the UDMA bit in the **RCGC2** register also writes the R0 bit in this register. If the UDMA bit is changed by writing to the **RCGC2** register, it can be read back correctly with a read of the **RCGC2** register. If software uses this register to control the clock for the  $\mu$ DMA module, the write causes proper operation, but the UDMA bit in the **RCGC2** register does not reflect the value of the R0 bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 53: Universal Asynchronous Receiver/Transmitter Run Mode Clock Gating Control (RCGCUART), offset 0x618

The **RCGCUART** register provides software the capability to enable and disable the UART modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the UART modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 54: Synchronous Serial Interface Run Mode Clock Gating Control (RCGCSSI), offset 0x61C

The **RCGCSSI** register provides software the capability to enable and disable the SSI modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the SSI modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 55: Inter-Integrated Circuit Run Mode Clock Gating Control (RCGCI2C), offset 0x620

The **RCGCI2C** register provides software the capability to enable and disable the I<sup>2</sup>C modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the I<sup>2</sup>C modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as I2C0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 56: Universal Serial Bus Run Mode Clock Gating Control (RCGCUSB), offset 0x628

The **RCGCUSB** register provides software the capability to enable and disable the USB module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the USB module. To support legacy software, the **RCGC2** register is available. A write to the USB0 bit in the **RCGC2** register also writes the R0 bit in this register. If the USB0 bit is changed by writing to the **RCGC2** register, it can be read back correctly with a read of the **RCGC2** register. If software uses this register to control the clock for the USB module, the write causes proper operation, but the USB0 bit in the **RCGC2** register does not reflect the value of the R0 bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 57: Controller Area Network Run Mode Clock Gating Control (RCGCCAN), offset 0x634

The **RCGCCAN** register provides software the capability to enable and disable the CAN modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the CAN modules. To support legacy software, the RCGC0 register is available. A write to the RCGC0 register also writes the corresponding bit in this register. Any bits that are changed by writing to the RCGC0 register can be read back correctly with a read of the RCGC0 register. If software uses this register to write a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the RCGC0 register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 58: Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC), offset 0x638

The **RCGCADC** register provides software the capability to enable and disable the ADC modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the ADC modules. To support legacy software, the RCGC0 register is available. A write to the RCGC0 register also writes the corresponding bit in this register. Any bits that are changed by writing to the RCGC0 register can be read back correctly with a read of the RCGC0 register. If software uses this register to write a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the RCGC0 register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 59: Analog Comparator Run Mode Clock Gating Control (RCGCACMP), offset 0x63C

The **RCGCACMP** register provides software the capability to enable and disable the analog comparator module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the analog comparator module. To support legacy software, the RCGC1 register is available. Setting any of the COMPn bits in the RCGC1 register also sets the R0 bit in this register. If any of the COMPn bits are set by writing to the RCGC1 register, it can be read back correctly when reading the RCGC1 register. If software uses this register to change the clocking for the analog comparator module, the write causes proper operation, but the value R0 is not reflected by the COMPn bits in the RCGC1 register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 60: Pulse Width Modulator Run Mode Clock Gating Control (RCGCPWM), offset 0x640

The **RCGCPWM** register provides software the capability to enable and disable the PWM modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the PWM modules. To support legacy software, the **RCGC0** register is available. A write to the PWM bit in the **RCGC0** register also writes the R0 bit in this register. If the PWM bit is changed by writing to the **RCGC0** register, it can be read back correctly with a read of the **RCGC0** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write to R0, the write causes proper operation, but the value of that bit is not reflected in the PWM bit in the **RCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 61: Quadrature Encoder Interface Run Mode Clock Gating Control (RCGCQEI), offset 0x644

The **RCGCQEI** register provides software the capability to enable and disable the QEI modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault. This register provides the same capability as the legacy **Run Mode Clock Gating Control Register n RCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **RCGCn** bits.

**Important:** This register should be used to control the clocking for the QEI modules. To support legacy software, the **RCGC1** register is available. A write to the **RCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **RCGC1** register can be read back correctly with a read of the **RCGC1** register. If software uses this register to write a legacy peripheral (such as QEI0), the write causes proper operation, but the value of that bit is not reflected in the **RCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 64: Watchdog Timer Sleep Mode Clock Gating Control (SCGCWD), offset 0x700

The **SCGCWD** register provides software the capability to enable and disable watchdog modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the watchdog modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 65: 16/32-Bit General-Purpose Timer Sleep Mode Clock Gating Control (SCGCTIMER), offset 0x704

The **SCGCTIMER** register provides software the capability to enable and disable 16/32-bit timer modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the timer modules. To support legacy software, the **SCGC1** register is available. A write to the **SCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC1** register can be read back correctly with a read of the **SCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 66: General-Purpose Input/Output Sleep Mode Clock Gating Control (SCGCGPIO), offset 0x708

The **SCGCGPIO** register provides software the capability to enable and disable GPIO modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the GPIO modules. To support legacy software, the **SCGC2** register is available. A write to the **SCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC2** register can be read back correctly with a read of the **SCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **SCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 67: Micro Direct Memory Access Sleep Mode Clock Gating Control (SCGCDMA), offset 0x70C

The **SCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module. To support legacy software, the **SCGC2** register is available. A write to the UDMA bit in the **SCGC2** register also writes the S0 bit in this register. If the UDMA bit is changed by writing to the **SCGC2** register, it can be read back correctly with a read of the **SCGC2** register. If software uses this register to control the clock for the  $\mu$ DMA module, the write causes proper operation, but the UDMA bit in the **SCGC2** register does not reflect the value of the S0 bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 68: Universal Asynchronous Receiver/Transmitter Sleep Mode Clock Gating Control (SCGCUART), offset 0x718

The **SCGCUART** register provides software the capability to enable and disable the UART modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the UART modules. To support legacy software, the **SCGC1** register is available. A write to the **SCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC1** register can be read back correctly with a read of the **SCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 69: Synchronous Serial Interface Sleep Mode Clock Gating Control (SCGCSSI), offset 0x71C

The **SCGCSSI** register provides software the capability to enable and disable the SSI modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the SSI modules. To support legacy software, the **SCGC1** register is available. A write to the **SCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC1** register can be read back correctly with a read of the **SCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 70: Inter-Integrated Circuit Sleep Mode Clock Gating Control (SCGCI2C), offset 0x720

The **SCGCI2C** register provides software the capability to enable and disable the I<sup>2</sup>C modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the I<sup>2</sup>C modules. To support legacy software, the **SCGC1** register is available. A write to the **SCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC1** register can be read back correctly with a read of the **SCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as I<sup>2</sup>C0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 71: Universal Serial Bus Sleep Mode Clock Gating Control (SCGCUSB), offset 0x728

The **SCGCUSB** register provides software the capability to enable and disable the USB module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the USB module. To support legacy software, the **SCGC2** register is available. A write to the USB0 bit in the **SCGC2** register also writes the S0 bit in this register. If the USB0 bit is changed by writing to the **SCGC2** register, it can be read back correctly with a read of the **SCGC2** register. If software uses this register to control the clock for the USB module, the write causes proper operation, but the USB0 bit in the **SCGC2** register does not reflect the value of the S0 bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 72: Controller Area Network Sleep Mode Clock Gating Control (SCGCCAN), offset 0x734

The **SCGCCAN** register provides software the capability to enable and disable the CAN modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the CAN modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 73: Analog-to-Digital Converter Sleep Mode Clock Gating Control (SCGCADC), offset 0x738

The **SCGCADC** register provides software the capability to enable and disable the ADC modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the ADC modules. To support legacy software, the **SCGC0** register is available. A write to the **SCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC0** register can be read back correctly with a read of the **SCGC0** register. If software uses this register to write a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 74: Analog Comparator Sleep Mode Clock Gating Control (SCGCACMP), offset 0x73C

The **SCGCACMP** register provides software the capability to enable and disable the analog comparator module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the analog comparator module. To support legacy software, the **SCGC1** register is available. Setting any of the COMPn bits in the SCGC1 register also sets the S0 bit in this register. If any of the COMPn bits are set by writing to the **SCGC1** register, it can be read back correctly when reading the **SCGC1** register. If software uses this register to change the clocking for the analog comparator module, the write causes proper operation, but the value S0 is not reflected by the COMPn bits in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 75: Pulse Width Modulator Sleep Mode Clock Gating Control (SCGCPWM), offset 0x740

The **SCGCPWM** register provides software the capability to enable and disable the PWM modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the PWM modules. To support legacy software, the **SCGC0** register is available. A write to the PWM bit in the **SCGC0** register also writes the S0 bit in this register. If the PWM bit is changed by writing to the SCGC0 register, it can be read back correctly with a read of the **SCGC0** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write to S0, the write causes proper operation, but the value of that bit is not reflected in the PWM bit in the **SCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 76: Quadrature Encoder Interface Sleep Mode Clock Gating Control (SCGCQEI), offset 0x744

The **SCGCQEI** register provides software the capability to enable and disable the QEI modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Sleep Mode Clock Gating Control Register n SCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **SCGCn** bits.

**Important:** This register should be used to control the clocking for the QEI modules. To support legacy software, the **SCGC1** register is available. A write to the **SCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **SCGC1** register can be read back correctly with a read of the **SCGC1** register. If software uses this register to write a legacy peripheral (such as QEI0), the write causes proper operation, but the value of that bit is not reflected in the **SCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 79: Watchdog Timer Deep-Sleep Mode Clock Gating Control (DCGCWD), offset 0x800

The **DCGCWD** register provides software the capability to enable and disable watchdog modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the watchdog modules. To support legacy software, the **DCGC0** register is available. A write to the **DCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC0** register can be read back correctly with a read of the **DCGC0** register. If software uses this register to write a legacy peripheral (such as Watchdog 0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 80: 16/32-Bit General-Purpose Timer Deep-Sleep Mode Clock Gating Control (DCGCTIMER), offset 0x804

The **DCGCTIMER** register provides software the capability to enable and disable 16/32-bit timer modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the timer modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as Timer 0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 81: General-Purpose Input/Output Deep-Sleep Mode Clock Gating Control (DCGCGPIO), offset 0x808

The **DCGCGPIO** register provides software the capability to enable and disable GPIO modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the GPIO modules. To support legacy software, the **DCGC2** register is available. A write to the **DCGC2** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC2** register can be read back correctly with a read of the **DCGC2** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as GPIO A), the write causes proper operation, but the value of that bit is not reflected in the **DCGC2** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 82: Micro Direct Memory Access Deep-Sleep Mode Clock Gating Control (DCGCDMA), offset 0x80C

The **DCGCDMA** register provides software the capability to enable and disable the  $\mu$ DMA module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the  $\mu$ DMA module. To support legacy software, the **DCGC2** register is available. A write to the UDMA bit in the **DCGC2** register also writes the D0 bit in this register. If the UDMA bit is changed by writing to the **DCGC2** register, it can be read back correctly with a read of the **DCGC2** register. If software uses this register to control the clock for the  $\mu$ DMA module, the write causes proper operation, but the UDMA bit in the **DCGC2** register does not reflect the value of the D0 bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 83: Universal Asynchronous Receiver/Transmitter Deep-Sleep Mode Clock Gating Control (DCGCUART), offset 0x818

The **DCGCUART** register provides software the capability to enable and disable the UART modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the UART modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as UART0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 84: Synchronous Serial Interface Deep-Sleep Mode Clock Gating Control (DCGCSSI), offset 0x81C

The **DCGCSSI** register provides software the capability to enable and disable the SSI modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the SSI modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as SSI0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 85: Inter-Integrated Circuit Deep-Sleep Mode Clock Gating Control (DCGCI2C), offset 0x820

The **DCGCI2C** register provides software the capability to enable and disable the I<sup>2</sup>C modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the I<sup>2</sup>C modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write a legacy peripheral (such as I<sup>2</sup>C0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 86: Universal Serial Bus Deep-Sleep Mode Clock Gating Control (DCGCUSB), offset 0x828

The **DCGCUSB** register provides software the capability to enable and disable the USB module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the USB module. To support legacy software, the **DCGC2** register is available. A write to the USB0 bit in the **DCGC2** register also writes the D0 bit in this register. If the USB0 bit is changed by writing to the **DCGC2** register, it can be read back correctly with a read of the **DCGC2** register. If software uses this register to control the clock for the USB module, the write causes proper operation, but the USB0 bit in the **DCGC2** register does not reflect the value of the D0 bit. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 87: Controller Area Network Deep-Sleep Mode Clock Gating Control (DCGCCAN), offset 0x834

The **DCGCCAN** register provides software the capability to enable and disable the CAN modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the CAN modules. To support legacy software, the **DCGC0** register is available. A write to the **DCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC0** register can be read back correctly with a read of the **DCGC0** register. If software uses this register to write a legacy peripheral (such as CAN0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 88: Analog-to-Digital Converter Deep-Sleep Mode Clock Gating Control (DCGCADC), offset 0x838

The **DCGCADC** register provides software the capability to enable and disable the ADC modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the ADC modules. To support legacy software, the **DCGC0** register is available. A write to the **DCGC0** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC0** register can be read back correctly with a read of the **DCGC0** register. If software uses this register to write a legacy peripheral (such as ADC0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 89: Analog Comparator Deep-Sleep Mode Clock Gating Control (DCGCACMP), offset 0x83C

The **DCGCACMP** register provides software the capability to enable and disable the analog comparator module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the analog comparator module. To support legacy software, the **DCGC1** register is available. Setting any of the COMPn bits in the **DCGC1** register also sets the D0 bit in this register. If any of the COMPn bits are set by writing to the **DCGC1** register, it can be read back correctly when reading the **DCGC1** register. If software uses this register to change the clocking for the analog comparator module, the write causes proper operation, but the value D0 is not reflected by the COMPn bits in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 90: Pulse Width Modulator Deep-Sleep Mode Clock Gating Control (DCGCPWM), offset 0x840

The **DCGCPWM** register provides software the capability to enable and disable the PWM modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the PWM modules. To support legacy software, the **DCGC0** register is available. A write to the PWM bit in the **DCGC0** register also writes the D0 bit in this register. If the PWM bit is changed by writing to the **DCGC0** register, it can be read back correctly with a read of the **DCGC0** register. Software must use this register to support modules that are not present in the legacy registers. If software uses this register to write to D0, the write causes proper operation, but the value of that bit is not reflected in the PWM bit in the **DCGC0** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 91: Quadrature Encoder Interface Deep-Sleep Mode Clock Gating Control (DCGCQEI), offset 0x844

The **DCGCQEI** register provides software the capability to enable and disable the QEI modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the watchdog modules and has the same bit polarity as the corresponding **DCGCn** bits.

**Important:** This register should be used to control the clocking for the QEI modules. To support legacy software, the **DCGC1** register is available. A write to the **DCGC1** register also writes the corresponding bit in this register. Any bits that are changed by writing to the **DCGC1** register can be read back correctly with a read of the **DCGC1** register. If software uses this register to write a legacy peripheral (such as QEI0), the write causes proper operation, but the value of that bit is not reflected in the **DCGC1** register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 93: 32/64-Bit Wide General-Purpose Timer Deep-Sleep Mode Clock Gating Control (DCGCWTIMER), offset 0x85C

The **DCGCWTIMER** register provides software the capability to enable and disable 32/64-bit wide timer modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power. This register provides the same capability as the legacy **Deep-Sleep Mode Clock Gating Control Register n DCGCn** registers specifically for the timer modules and has the same bit polarity as the corresponding **DCGCn** bits.

## Register 94: Watchdog Timer Power Control (PCWD), offset 0x900

The **PCWD** register controls the power provided to the watchdog modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRWD** register if the active mode changes and the corresponding bit in the **RCGCWD**, **SCGCWD**, or **DCGCWD** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The watchdog modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

## Register 95: 16/32-Bit General-Purpose Timer Power Control (PCTIMER), offset 0x904

The **PCTIMER** register controls the power provided to the 16/32-bit timer modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding modules state is not retained. Software should perform a peripheral reset using the **SRTIMER** register if the active mode changes and the corresponding bit in the **RCGCTIMER**, **SCGCTIMER**, or **DCGCTIMER** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The timer modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

### 16/32-Bit General-Purpose Timer Power Control (PCTIMER)

## Register 96: General-Purpose Input/Output Power Control (PCGPIO), offset 0x908

The **PCGPIO** register controls the power provided to the GPIO modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRGPIO** register if the active mode changes and the corresponding bit in the **RCGCGPIO**, **SCGCGPIO**, or **DCGCGPIO** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The GPIO modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

### General-Purpose Input/Output Power Control (PCGPIO)

Base 0x400F.E000

Offset 0x908

Type R/W, reset 0x0000.7FFF

## Register 97: Micro Direct Memory Access Power Control (PCDMA), offset 0x90C

The **PCDMA** register controls the power provided to the  $\mu$ DMA module. Clearing the bit corresponding to the module indicates to the hardware that firmware requests that the peripheral be unpowered. When the bit in this register is set, the module's state is not retained. Software should perform a peripheral reset using the **SRDMA** register if the active mode changes and the corresponding bit in the **RCGCDMA**, **SCGCDMA**, or **DCGCDMA** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The  $\mu$ DMA module does not currently have the ability to respond to the power down request. Setting the bit in this register has no effect on power consumption. This register is provided for future software compatibility.

### Micro Direct Memory Access Power Control (PCDMA)

Base 0x400F.E000

Offset 0x90C

#### Value Description

- |   |                                                                                                                                                                                                                                                             |
|---|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | The $\mu$ DMA module is powered, but does not receive a clock. In this case, the module is inactive.<br><br>This configuration provides the second-lowest power consumption of the module because it consumes only leakage current.                         |
| 0 | The $\mu$ DMA module is not powered and does not receive a clock. In this case, the module's state is not retained.<br><br>This configuration provides the lowest power consumption state of the module because it consumes no dynamic nor leakage current. |

## Register 98: Universal Asynchronous Receiver/Transmitter Power Control (PCUART), offset 0x918

The **PCUART** register controls the power provided to the UART modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRUART** register if the active mode changes and the corresponding bit in the **RCGCUART**, **SCGCUART**, or **DCGCUART** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The UART modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

### Universal Asynchronous Receiver/Transmitter Power Control (PCUART)

Base 0x400F.E000

Offset 0x918

Type R/W, reset 0x0000.00FF

**Register 99: Synchronous Serial Interface Power Control (PCSSI), offset 0x91C**

The **PCSSI** register controls the power provided to the SSI modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRSSI** register if the active mode changes and the corresponding bit in the **RCGCSI**, **SCGCSI**, or **DCGCSI** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The SSI modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

**Synchronous Serial Interface Power Control (PCSSI)**

Base 0x400F.E000

## Register 100: Inter-Integrated Circuit Power Control (PCI2C), offset 0x920

The **PCI2C** register controls the power provided to the I<sup>2</sup>C modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRI2C** register if the active mode changes and the corresponding bit in the **RCGCI2C**, **SCGCI2C**, or **DCGCI2C** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The I<sup>2</sup>C modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

### Inter-Integrated Circuit Power Control (PCI2C)

Base 0x400F.E000

Offset 0x920

## Register 101: Universal Serial Bus Power Control (PCUSB), offset 0x928

The **PCUSB** register controls the power provided to the USB module. Clearing the bit corresponding to the module indicates to the hardware that firmware requests that the peripheral be unpowered. When the bit in this register is set, the module's state is not retained. Software should perform a peripheral reset using the **SRUSB** register if the active mode changes and the corresponding bit in the **RCGCUSB**, **SCGCUSB**, or **DCGCUSB** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

## Register 102: Controller Area Network Power Control (PCCAN), offset 0x934

The **PCCAN** register controls the power provided to the CAN modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRCAN** register if the active mode changes and the corresponding bit in the **RCGCCAN**, **SCGCCAN**, or **DCGCCAN** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

## Register 103: Analog-to-Digital Converter Power Control (PCADC), offset 0x938

The **PCADC** register controls the power provided to the ADC modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRADC** register if the active mode changes and the corresponding bit in the **RCGCADC**, **SCGCADC**, or **DCGCADC** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The ADC modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

## Register 104: Analog Comparator Power Control (PCACMP), offset 0x93C

The **PCACMP** register controls the power provided to the analog comparator module. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRACMP** register if the active mode changes and the corresponding bit in the **RCGCACMP**, **SCGCACMP**, or **DCGCACMP** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The analog comparator module does not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | The analog comparator module is powered, but does not receive a clock. In this case, the module is inactive.<br>This configuration provides the second-lowest power consumption of the module because it consumes only leakage current.                         |
| 0 | The analog comparator module is not powered and does not receive a clock. In this case, the module's state is not retained.<br>This configuration provides the lowest power consumption state of the module because it consumes no dynamic nor leakage current. |

**Register 105: Pulse Width Modulator Power Control (PCPWM), offset 0x940**

The **PCPWM** register controls the power provided to the PWM modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRPWM** register if the active mode changes and the corresponding bit in the **RCGCPWM**, **SCGCPWM**, or **DCGCPWM** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The PWM modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

## Register 106: Quadrature Encoder Interface Power Control (PCQEI), offset 0x944

The **PCQEI** register controls the power provided to the QEI modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding module's state is not retained. Software should perform a peripheral reset using the **SRQEI** register if the active mode changes and the corresponding bit in the **RCGCQEI**, **SCGCQEI**, or **DCGCQEI** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The QEI modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

**Register 107: EEPROM Power Control (PCEEPROM), offset 0x958**

The **PCEEPROM** register controls the power provided to the EEPROM module. Clearing the bit corresponding to the module indicates to the hardware that firmware requests that the peripheral be unpowered. When the bit in this register is set, the module's state is not retained. Software should perform a peripheral reset using the **SREEPROM** register if the active mode changes and the corresponding bit in the **RCGCEEPROM**, **SCGCEEPROM**, or **DCGCEEPROM** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The EEPROM module does not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

## Register 108: 32/64-Bit Wide General-Purpose Timer Power Control (PCWTIMER), offset 0x95C

The **PCWTIMER** register controls the power provided to the 32/64-bit wide timer modules. Clearing the bit corresponding to one of the modules indicates to the hardware that firmware requests that the peripheral be unpowered. When a bit in this register is set, the corresponding modules state is not retained. Software should perform a peripheral reset using the **SRWTIMER** register if the active mode changes and the corresponding bit in the **RCGCWTIMER**, **SCGCWTIMER**, or **DCGCWTIMER** register is a 1 or the Pn bit is changed from a 0 to a 1. Software must re-initialize the module when re-enabled due to the loss of state.

**Note:** The timer modules do not currently have the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is provided for future software compatibility.

### 32/64-Bit Wide General-Purpose Timer Power Control (PCWTIMER)

Base 0x400F.E000

Offset 0x95C

**Register 109: Watchdog Timer Peripheral Ready (PRWD), offset 0xA00**

The **PRWD** register indicates whether the watchdog modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCWD** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCWD** bit is changed. A reset change is initiated if the corresponding **SRWD** bit is changed from 0 to 1.

The **PRWD** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## Register 110: 16/32-Bit General-Purpose Timer Peripheral Ready (PRTIMER), offset 0xA04

The **PRTIMER** register indicates whether the timer modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCTIMER** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCTIMER** bit is changed. A reset change is initiated if the corresponding **SRTIMER** bit is changed from 0 to 1.

The **PRTIMER** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## Register 111: General-Purpose Input/Output Peripheral Ready (PRGPIO), offset 0xA08

The **PRGPIO** register indicates whether the GPIO modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCGPIO** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCGPIO** bit is changed. A reset change is initiated if the corresponding **SRGPIO** bit is changed from 0 to 1.

The **PRGPIO** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## Register 112: Micro Direct Memory Access Peripheral Ready (PRDMA), offset 0xA0C

The **PRDMA** register indicates whether the  $\mu$ DMA module is ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCDMA** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCDMA** bit is changed. A reset change is initiated if the corresponding **SRDMA** bit is changed from 0 to 1.

The **PRDMA** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## Register 113: Universal Asynchronous Receiver/Transmitter Peripheral Ready (PRUART), offset 0xA18

The **PRUART** register indicates whether the UART modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCUART** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCUART** bit is changed. A reset change is initiated if the corresponding **SRUART** bit is changed from 0 to 1.

The **PRUART** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## Register 114: Synchronous Serial Interface Peripheral Ready (PRSSI), offset 0xA1C

The **PRSSI** register indicates whether the SSI modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCSSI** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCSI** bit is changed. A reset change is initiated if the corresponding **SRSSI** bit is changed from 0 to 1.

The **PRSSI** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

**Register 115: Inter-Integrated Circuit Peripheral Ready (PRI2C), offset 0xA20**

The **PRI2C** register indicates whether the I<sup>2</sup>C modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCI2C** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCI2C** bit is changed. A reset change is initiated if the corresponding **SRI2C** bit is changed from 0 to 1.

The **PRI2C** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

**Register 116: Universal Serial Bus Peripheral Ready (PRUSB), offset 0xA28**

The **PRUSB** register indicates whether the USB module is ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCUSB** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCUSB** bit is changed. A reset change is initiated if the corresponding **SRUSB** bit is changed from 0 to 1.

The **PRUSB** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## Register 118: Analog-to-Digital Converter Peripheral Ready (PRADC), offset 0xA38

The **PRADC** register indicates whether the ADC modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCADC** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCADC** bit is changed. A reset change is initiated if the corresponding **SRADC** bit is changed from 0 to 1.

The **PRADC** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

**Register 119: Analog Comparator Peripheral Ready (PRACMP), offset 0xA3C**

The **PRACMP** register indicates whether the analog comparator module is ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCACMP** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCACMP** bit is changed. A reset change is initiated if the corresponding **SRACMP** bit is changed from 0 to 1.

The **PRACMP** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## Register 123: 32/64-Bit Wide General-Purpose Timer Peripheral Ready (PRWTIMER), offset 0xA5C

The **PRWTIMER** register indicates whether the timer modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCWTIMER** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCWTIMER** bit is changed. A reset change is initiated if the corresponding **SRWTIMER** bit is changed from 0 to 1.

The **PRWTIMER** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

## 5.6 System Control Legacy Register Descriptions

All addresses given are relative to the System Control base address of 0x400F.E000.

**Important:** Register in this section are provided for legacy software support only; registers in “System Control Register Descriptions” on page 235 should be used instead.

## Register 124: Device Capabilities 0 (DC0), offset 0x008

This legacy register is predefined by the part and can be used to verify features.

**Important:** This register is provided for legacy software support only.

The **Flash Size (FSIZE)** and **SRAM Size (SSIZE)** registers should be used to determine this microcontroller's memory sizes. A read of **DC0** correctly identifies legacy memory sizes but software must use **FSIZE** and **SSIZE** for memory sizes that are not listed below.

### Device Capabilities 0 (DC0)

## Register 125: Device Capabilities 1 (DC1), offset 0x010

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC0**, **SCGC0**, **DCGC0**, and the peripheral-specific **RCGC**, **SCGC**, and **DCGC** registers cannot be set.

**Important:** This register is provided for legacy software support only.

The Peripheral Present registers should be used to determine which modules are implemented on this microcontroller. A read of **DC1** correctly identifies if a legacy module is present but software must use the Peripheral Present registers to determine if a module is present that is not supported by the **DCn** registers.

Likewise, the **ADC Peripheral Properties (ADCPP)** register should be used to determine the maximum ADC sample rate and whether the temperature sensor is present. However, to support legacy software, the MAXADCnSPD fields and the TEMPSNS bit are available. A read of **DC1** correctly identifies the maximum ADC sample rate for legacy rates and whether the temperature sensor is present.

## Register 126: Device Capabilities 2 (DC2), offset 0x014

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC1**, **SCGC1**, **DCGC1**, and the peripheral-specific **RCGC**, **SCGC**, and **DCGC** registers cannot be set.

**Important:** This register is provided for legacy software support only.

The Peripheral Present registers should be used to determine which modules are implemented on this microcontroller. A read of **DC2** correctly identifies if a legacy module is present but software must use the Peripheral Present registers to determine if a module is present that is not supported by the **DCn** registers.

Note that the **Analog Comparator Peripheral Present (PPACMP)** register identifies whether the analog comparator module is present. The **Analog Comparator Peripheral Properties (ACMPPP)** register indicates how many analog comparator blocks are present in the module.

## Register 127: Device Capabilities 3 (DC3), offset 0x018

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the feature is not present.

**Important:** This register is provided for legacy software support only.

For some modules, the peripheral-resident Peripheral Properties registers should be used to determine which pins are available on this microcontroller. A read of **DC3** correctly identifies if a legacy pin is present but software must use the Peripheral Properties registers to determine if a pin is present that is not supported by the **DCn** registers.

### Device Capabilities 3 (DC3)

Base 0x400F.E000

## Register 128: Device Capabilities 4 (DC4), offset 0x01C

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC2**, **SCGC2**, **DCGC2**, and the peripheral-specific **RCGC**, **SCGC**, and **DCGC** registers cannot be set.

**Important:** This register is provided for legacy software support only.

The Peripheral Present registers should be used to determine which modules are implemented on this microcontroller. A read of **DC4** correctly identifies if a legacy module is present but software must use the Peripheral Present registers to determine if a module is present that is not supported by the **DCn** registers.

The peripheral-resident Peripheral Properties registers should be used to determine which pins and features are available on this microcontroller. A read of **DC4** correctly identifies if a legacy pin or feature is present. Software must use the Peripheral Properties registers to determine if a pin or feature is present that is not supported by the **DCn** registers.

## Register 129: Device Capabilities 5 (DC5), offset 0x020

This register is predefined by the part and can be used to verify PWM features. If any bit is clear in this register, the module is not present.

**Important:** This register is provided for legacy software support only.

The **PWM Peripheral Properties (PWMPP)** register should be used to determine what pins and features are available on PWM modules. A read of this register correctly identifies if a legacy pin or feature is present. Software must use the **PWMPP** register to determine if a pin or feature that is not supported by the **DCn** registers is present.

## Register 130: Device Capabilities 6 (DC6), offset 0x024

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the **RCGC0**, **SCGC0**, and **DCGC0** registers cannot be set.

**Important:** This register is provided for legacy software support only.

The **USB Peripheral Properties (USBPP)** register should be used to determine what features are available on the USB module. A read of this register correctly identifies if a legacy feature is present. Software must use the **USBPP** register to determine if a pin or feature that is not supported by the **DCn** registers is present.

## Register 131: Device Capabilities 7 (DC7), offset 0x028

This register is predefined by the part and can be used to verify  $\mu$ DMA channel features. A 1 indicates the channel is available on this device; a 0 that the channel is only available on other devices in the family. Channels can have multiple assignments, see “Channel Assignments” on page 561 for more information.

**Important:** This register is provided for legacy software support only. The DMACHANS bit field in the **DMA Status (DMASTAT)** register indicates the number of DMA channels.

## Register 132: Device Capabilities 8 (DC8), offset 0x02C

This register is predefined by the part and can be used to verify features.

**Important:** This register is provided for legacy software support only.

The **ADC Peripheral Properties (ADCPP)** register should be used to determine how many input channels are available on the ADC module. A read of this register correctly identifies if legacy channels are present but software must use the **ADCPP** register to determine if a channel is present that is not supported by the **DCn** registers.

## Register 133: Software Reset Control 0 (SRCR0), offset 0x040

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 1 (DC1)** register.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Software Reset registers (such as **SRWD**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this legacy register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 134: Software Reset Control 1 (SRCR1), offset 0x044

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 2 (DC2)** register.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Software Reset registers (such as **SRTIMER**) should be used to reset specific peripherals. A write to this register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as **TIMER0**), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Note that the **Software Reset Analog Comparator (SRACMP)** register has only one bit to set the analog comparator module. Resetting the module resets all the blocks. If any of the **COMPn** bits are set, the entire analog comparator module is reset. It is not possible to reset the blocks individually.

## Register 135: Software Reset Control 2 (SRCR2), offset 0x048

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 4 (DC4)** register.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Software Reset registers (such as **SRDMA**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as the  $\mu$ DMA), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

## Register 136: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes. Note that there must be a delay of 3 system clocks after a module clock is enabled before any registers in that module are accessed.

**Important:** This register is provided for legacy software support only.

The peripheral-specific Run Mode Clock Gating Control registers (such as **RCGCWD**) should be used to reset specific peripherals. A write to this legacy register also writes the corresponding bit in the peripheral-specific register. Any bits that are changed by writing to this register can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support modules that are not present in the legacy registers. If software uses a peripheral-specific register to write a legacy peripheral (such as Watchdog 1), the write causes proper operation, but the value of that bit is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.

Likewise, the **ADC Peripheral Configuration (ADCPC)** register should be used to configure the ADC sample rate. However, to support legacy software, the MAXADCnSPD fields are available. A write to these legacy fields also writes the corresponding field in the peripheral-specific register. If a field is changed by writing to this register, it can be read back correctly with a read of this register. Software must use the peripheral-specific registers to support rates that are not available in this register. If software uses a peripheral-specific register to set the ADC rate, the write causes proper operation, but the value of that field is not reflected in this register. If software uses both legacy and peripheral-specific register accesses, the peripheral-specific registers must be accessed by read-modify-write operations that affect only peripherals that are not present in the legacy registers. In this manner, both the peripheral-specific and legacy registers have coherent information.
